& Sons, 11 and 12, Cornhill, London, E.C.

ADVERTISERS are requested to note that
although we do not object to receive Letters to be called
for, we cannot undertake to forward them.

PARTNERSHIP.—A Nurseryman, carrying
on a successful business within 25 miles of London, is
desirous of meeting with a Partner. Failing health causes
Advertiser to wish to find a man, or men who in, say, one
or two years would be able to take over from him the entire busi-
ness. Money would be required, but every facility be afforded
provided substantial guarantees were given. The fullest refer-
ences given and required.—Address, by letter, giving outline
of means and position, **NURSEYMAN**, Messrs. Norris,
Allens & Carter, Solicitors, 20, Bedford Row, London, W.C.

WANTED, a HEAD GARDENER, who
thoroughly understands every branch of Forcing, and
Orchard-house and Greenhouse Management. Character must
bear the strictest enquiry as to sobriety, honesty, and capa-
bility.—Address, stating full particulars as to age, family,
wages, &c., **MAJOR HARE**, Docking, King's Lynn.

**WANTED, a SINGLE-HANDED GAR-
DENER; a good Cricketer preferred.**—W. B. G.
Carter & Co., Printers and Stationers, Rickmansworth, Herts.

WANTED, as GARDENER, a married
man, without family; age from 35 to 45; must be
thoroughly practical in every branch. Wages, 24s., with
lodge. A second Man kept.—M., Faulkner, Waterloo Station,
London, S.E.

WANTED, an UNDER GARDENER,
with a Wife or Mother, to live with him, rent free, in
the lodge, and attend to the Gate; he must be able to take
Charge of a Cow.—Apply, by letter, stating number and age of
children, if any length of character, age, and wages required,
to Mr. MORRIS, Grove House, South Wimbledon, S.W.

WANTED, an experienced OUTDOOR
NURSEY FOREMAN and SALESMAN. Liberal
wages to a competent Man.—R. THORNHILL, Bowdon
Nurseries, Bowdon, Manchester.

Propagator of Roses, Rhododendrons, &c.
PAUL and SON want a clever, experienced
Man, as Propagator (Indoors) of Roses, General Hardy
Stuff, and Soft-wooded Plants. Efficient help and every en-
couragement given to a really painstaking Man.—Apply, by
letter, to The Old Nurseries, Cheshunt, N.

**WANTED, a young Man, as SOFT-
WOODED PROPAGATOR and GROWER.**—E.
COOLING, Mile Ash Nurseries, Derby.

MR. G. WHEELER is in WANT of a respectable Young MAN, to Take Charge of a Collection of Stove and Greenhouse Plants and Conservatory, and to Work in the Flower Garden occasionally. Wages, 22s. per week.—St. John's Lodge, Regent's Park, N.W.

WANTED, an experienced PACKER of General Nursery Stock.—Apply, in own handwriting, stating wages, references, and where last employed, to CRANSTON AND CO., King's Acre Nurseries, Hereford.

WANTED, a CORRESPONDING CLERK and BOOK-KEEPER; must be well acquainted with the Nursery Business, and competent to take the Entire Correspondence, and occasionally to Travel. Unexceptionable references required.—Apply, stating salary required, &c., to CRANSTON AND CO., King's Acre Nurseries, Hereford.

Seed Trade.
WANTED, IMMEDIATELY, a thoroughly efficient and smart COUNTER-HAND; one who has been regularly trained to the business in a large, well-regulated establishment. Address stating age, references, salary expected, and when present engagement expires, M. M., *Gardeners' Chronicle* Office, W.C.

WANTED, an ASSISTANT SHOPMAN, and also to Assist at the Books; a good Penman, quick at Accounts, indispensable.—Apply, in own handwriting, with references, to JOHN SHAW AND CO., Seed Merchants, Oxford Street, Manchester.

WANTED, a THIRD SHOPMAN, for the Wholesale Seed Trade in a London House.—Reply, stating experience, age, and salary required, to A. B., Howcroft & Watkins, 14, Tavistock Row, Covent Garden, London, W.C.

WANTED, a JUNIOR SHOPMAN.—EDMONDSON BROTHERS, 10, Dame Street, Dublin.

WANT PLACES.

Head Gardeners.

JOHN LAING AND CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for First-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stansted Park and Rutland Park Nurseries, Forest Hill, London, S.E.

E. G. HENDERSON AND SON have many excellent GARDENERS with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filler of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

E. P. DIXON can at present recommend several excellent GARDENERS, and will be pleased to answer any enquiries from Ladies and Gentlemen requiring such.—The Yorkshire Seed Establishment, Hull.

GARDENER (HEAD).—Age 36, married, two children; thorough practical experience in all branches of the profession. Four years' character. Please state particulars.—T. WOOD, Anstey Manor, Alton, Hants.

To Noblemen and Gentlemen.

GARDENER (HEAD).—Age 32, married; thoroughly experienced in all branches of the profession. Can be highly recommended.—C. B., 52, Moffat Road, Thornton Heath, Croydon, Surrey.

GARDENER (HEAD), where two or three are kept.—Age 26, single; understands Vines, Melons, Cucumbers, Stove and Greenhouse Plants, &c. Good reference. Please state wages.—J. E. T., West Street, Great Marlow, Bucks.

GARDENER (HEAD).—Age 32, married, two children; thoroughly practical in all branches of the profession. Three and a half years' good character. Please state particulars.—W. G. H., Filsham Cottage, St. Leonards-on-Sea, Sussex.

GARDENER (HEAD).—Single; many years' experience in the Cultivation of all kinds of Fruits, Flowers, and Kitchen Gardening. Known to some of the leading Nurserymen in London. Good references.—E. B., Mr. McLaren, News Agent, Hammersmith, W.

GARDENER (HEAD).—Age 32, married; has a thorough knowledge of Pines, Grapes, Peaches, Cucumbers, Melons, &c.; is a good Plant Grower, Flower and Kitchen Gardener. Five years' good character from last employer.—W. P., 13, Union Place, St. Leonard's Road, Weymouth.

GARDENER (HEAD), in a small place, or FOREMAN in a large establishment.—Age 24; has had eight years' practical experience, three as Foreman in the houses. Can be highly recommended for abilities and general character.—T. COVSH, Jun., E. Wood, Esq., Newbold Revel, Rugby.

GARDENER (HEAD).—Age 39, married; thoroughly understands Vines, Pines, Cucumbers, Melons, Stove and Greenhouse Plants, and Kitchen Gardening. Nine years' good character from last employer. Nineteen years' experience in large establishments. No single-handed place accepted.—T. STEVENS, 11, Warren Road, Reigate.

GARDENER (HEAD), where three or more are kept.—Age 30, married; Scotch; fourteen years' experience; understands Gardening in all its branches, and could take the Management of a small Estate. Open for engagement about the beginning of November next. First-class references.—T. MCK., The Gardens, Ayton, Bridge of Earn, Perthshire, N.B.

GARDENER (HEAD, WORKING), where two or more are kept.—Age 27, single; ten years' experience.—W. A. KIDD, 34, Bishops Road, North Brixton, S.W.

GARDENER (HEAD, WORKING).—Single; twenty years' practical knowledge of the profession in all its branches. Character will bear the strictest investigation.—A. B., 48, Cochrane Street, St. John's Wood, London, N.W.

GARDENER (HEAD, WORKING).—Age 27, single; thorough practical knowledge of the profession in all its branches. Good character and testimonials.—H. DOBBIE, The Gardens, Cranfield Court, Newport Pagnell, Bucks.

GARDENER (HEAD, WORKING).—Middle-aged; could Superintend a small Farm as well. Wife a first-class Laundress or Dairywoman, or could take Charge of a Gentleman's House. Good testimonials.—GARDENER, 19, Kemp Place, Glen Ogle Road, Edinburgh.

GARDENER (HEAD, WORKING).—Age 32, married, one child; thoroughly understands Forcing of Fruits, Flowers, and the General Routine of Gardening. No objection to Land and Stock.—A. B., 2, Sarah Cottage, Hawk's Road, Norbiton, Kingston-on-Thames, Surrey.

GARDENER (HEAD, WORKING).—Age 26, married; understands Stove and Greenhouse Plants, Vines, Peaches, Melons, Cucumbers, Flower and Kitchen Gardening. Good references.—A. B., Post-office, Barford, Warwick.

GARDENER (HEAD, WORKING), where two or more are kept.—Age 35, married, small family; understands the profession in all its branches, also Land and Stock. Eleven years' good character from present place.—W. B., Worlingworth, Wickham Market.

GARDENER (HEAD, WORKING).—Age 29, married, one child; has had much practical experience in the Cultivation of all kinds of Plants, Fruits, and Vegetables; is well up in Modern Flower Gardening, Dinner-table Decoration, and the Laying-out of New Grounds. Total abstinence. Can be well recommended for honesty and capability.—P. W., M. Groundwell, Scott Hall Cottage, Woodhouse Carr, Leeds.

GARDENER (HEAD), and BAILIFF.—JOHN KITLEY, Head Gardener and Bailiff to Sir J. P. Grant for the past twelve years, is open to a re-engagement. Highly recommended.—Prospect House, Bath.

GARDENER (HEAD, or SINGLE-HANDED).—Age 25, married; understands Gardening in all its branches. Good character.—H. L., 3, Shire Hall Lane, Hendon, N.W.

GARDENER.—Understands Kitchen Garden, Flowers, &c., also the Management of Land. Ten years' reference.—G. A. H., Post-office, Leominster.

GARDENER (SINGLE-HANDED).—Age 21; understands Stove and Greenhouse Plants, and Flower Garden. Good character.—A. B., 12, Portland Street, Brighton.

GARDENER (SINGLE-HANDED, or where a lad is kept).—Age 27, married, no family. Unexceptionable references.—THOMAS JOHNSON, Haybrow, Hackness, Scarborough, Yorkshire.

GARDENER (SINGLE-HANDED).—Age 28, married, one child; fourteen years' experience; understands Vines, Cucumbers, Melons, Greenhouses, Fruit, Flower and Kitchen Gardens. Good character.—GARDENER, Scremby Hall, Spilsby, Lincolnshire.

GARDENER (UNDER).—Age 21; six years' experience, and three years' good character from last place.—J. B., Moor Street, Kidlington.

GARDENER (UNDER).—Age 21. No objection to Cows or Poultry.—J. T., Greenford Lodge, near Southall, Middlesex.

GARDENER (UNDER), under a Foreman preferred.—Age 18, understands Forcing Fruit, choice Vegetables, Pines, &c. Can be well recommended.—The GARDENER, Aston-on-Trent, Derby.

GARDENER (UNDER), under a Foreman, where he will be able to improve.—Age 20. Twelve months' good character from present situation.—T. B., Rendcomb Gardens, Cirencester.

GARDENER (UNDER), in a Gentleman's Establishment, in the Houses preferred.—Age 23. Please state wages.—J. SWINSON, Stanton Garden, Baweell, Derbyshire.

GARDENER (UNDER), age 17.—A LADY wishes to recommend a young Man as above, who wishes to improve his knowledge of Gardening; he is trustworthy, industrious, and intelligent.—Miss FORSTER, Penn, Amersham.

GARDENER (UNDER), or JOURNEYMAN in a Nobleman's or Gentleman's Garden.—Age 22. Good reference.—Address, with particulars, to J. D., 39, Cochrane Street, St. John's Wood, London, N.W.

To Nurserymen.

FOREMAN (OUTDOOR).—Age 26; experienced Knifeman; has good knowledge of the general routine of Nursery Work. Good reference.—A. B., 71, Speke Road, Clapham Junction, S.W.

FOREMAN, in a good Establishment, age 24.—A Bonus will be given to any person procuring Advertiser a good situation as above; has had nine years' good experience in all branches, well up in Plant and Fruit Growing. Can be highly recommended. First-class character.—Address, with particulars, to MELVILLE, 37, Barrow Hill Road, St. John's Wood, London, N.W.

FOREMAN, or SECOND, in a Gentleman's Garden.—Age 24; has a good general knowledge of the profession. Three years' good character.—K., 1, Clifton Terrace, Nightingale Road, Wood Green, N.

PROPAGATOR (UNDER), or as ASSISTANT.—Age 24; good experience. References from present employer.—J. J., 10, Essenden Terrace, Plumstead Road, Kent, S. E.

To Nurserymen.

PROPAGATOR, or WORKING FOREMAN and PROPAGATOR, where Plants are grown in large quantities.—Thoroughly experienced in Indoor and Outdoor Propagation. Good and reliable references can be obtained.—A. B., 20, Vining Street, Atlantic Road, Brixton, London, S.W.

PROPAGATOR and GROWER.—Great experience in Growing for Exhibition, also a thorough knowledge of Growing and Forcing for all Market purposes. First-class references.—A. B., 435, Edgware Road, W.

To Nurserymen.

PROPAGATOR of Stove and Greenhouse Plants, Roses, Conifers, Clematis, and Rhododendrons. Ten years' good character from last situation (Luncombe, Pince & Co., Exeter Nurseries).—SAMUEL POPE, 1, Pince's Cottages, Alphington Road, St. Thomas, Exeter.

To the Trade.

PROPAGATOR (ASSISTANT), under a good Foreman.—Age 21; understands Hard and Soft-wooded, Indoor, and General Nursery Work. Three years' character.—W. G., Percival Cottages, Merton, S.W.

JOURNEYMAN, in the Houses.—Age 20. Good references.—W. SMITH, Court Gardens, Great Marlow, Bucks.

JOURNEYMAN (Indoors preferred).—Age 22; understands Flower and Kitchen Garden Plants, and Forcing. Three years' good character.—J. WATSON, Cusworth Park Gardens, Doncaster.

JOURNEYMAN, in a Nobleman's or Gentleman's Establishment.—Age 24; six years' experience in Vines, Pines, Peaches, Cucumbers, Stove and Greenhouse Plants, &c.—J. BIRCH, Hewell Lane, Bromsgrove, Worcestershire.

IMPROVER, in a large Establishment.—Age 21; four years in last situation, chiefly under Glass. Good character.—G. H., Post-office, 1, Preston Road, Brighton.

IMPROVER, in a good Establishment, in the Houses.—Age 18; has a fair knowledge of General Work.—Apply, stating full particulars, to H. GRANT, Gardener, The Elms, Chelmsford, Essex.

IMPROVER, in a Gentleman's Garden.—Age 19; steady; three years' experience in Houses and Gardens. Good character.—A. D., The Gardens, East Head, Wokingham, Berks.

NURSERY MANAGER, CORRESPONDENT, or Occasional TRAVELLER.—Age 36; well up in all Nursery and Seed Departments, especially Rose Cultivation, &c. Unexceptionable references.—A. E., Mr. Godwin, Rose Nursery, Edmonton.

MANAGER, BOOK-KEEPER, CLERK, or SHOPMAN, in a Nursery or Seed Business.—Age 32. First-class references.—K. W., Strontian Lodge, Cotham, Bristol.

SHOPMAN (SECOND).—Age 22; nine years' experience in Scotland and Ireland. First-class references.—ALPHA, Messrs. Huist & Son, 6, Leadenhall Street, London, E.C.

SHOPMAN (ASSISTANT), in Wholesale Warehouse, or BOOK-KEEPER.—Age 27; has a good knowledge of the Seed Trade.—J. FALCONER, St. Nicholas, Richmond, Yorkshire.

TO FLORISTS and FRUITERS.—A Man, age 32, requires a situation as above; has had some experience, would make himself generally useful; writes a Bold Hand. Moderate wages.—ASTRACHAN, 16, Palatinat, New Kent Road, S.E.

To the Nursery and Seed Trade.

AGENCY, in Ireland only, Wanted by Advertiser, who is well known in the Trade, and has an extensive and valuable connection.—Please state terms, &c., to HORTUS, 117, Upper Rathuines.

KINAHAN'S LL WHISKY. Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

DINNEFORD'S FLUID MAGNESIA. The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants. DINNEFORD AND CO., 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S PILLS.—Wrong made Right.—Every day that any bodily suffering is permitted to continue renders it more certain to become chronic or dangerous. Holloway's Purifying, Cooling, and Strengthening PILLS are well adapted for any irregularity of the human body, and should be taken when the Stomach is Disordered, the Liver Deranged, the Kidneys inactive, the Bowels Torpid, or the Brain Muddled. With this Medicine every invalid can Cure Himself, and those who are weak and infirm through imperfect digestion may make themselves Strong and Stout by HOLLOWAY'S excellent PILLS. A few doses of them usually mitigate the most painful symptoms caused by indigestible food, from which they thoroughly free the alimentary canal and completely restore its natural power and action.

J. WEEKS & CO.'S ADDRESS.

J. WEEKS & CO.'S ADDRESS

To the Nobility, Gentry, and their Friends.

ENCOURAGED by the support hitherto accorded us, we beg to announce that we are now issuing a new and beautifully illustrated Catalogue of Ornamental Conservatories, which we confidently hope will satisfy the advanced and somewhat fastidious taste of the present age. It is now upwards of fifty years since our business was first established, and in that time what improvements in the tastes and habits of the nation have taken place! Then four brick walls with holes in them at intervals, without any attempt at ornament, met the views of the wealthy Englishman with regard to the external appearance of his dwelling; now he builds for himself a mansion of imposing or picturesque elevation, enriched with costly marbles and adorned with choicest specimens of the sculptor's art. Then the common objects of household use were badly finished, often ill-adapted to their purpose, and generally ugly; now perfection is the goal aimed at, and beauty and utility go hand in hand. Then Conservatories were simply regarded as places to shelter plants, and were, with a few exceptions, very commonplace structures; now the fact that appropriate architectural accessories greatly enhance the effect of flowers and plants is universally admitted, and the erection of elegant and costly buildings is the result. If it be true, as some one has said, that the character of an individual is best known by his pleasures, how great an elevation has the character of the nation undergone within that period, and how greatly has horticulture benefited by the change! Then the national pleasures were mostly inelegant and often coarse; now they are much more refined. Then Horticulture was regarded as a science very well for professional gardeners, and but rarely practised by amateurs; now it has become a popular and fashionable recreation. Then a Conservatory was the exception, and was usually a glasshouse of unornamental character at some distance from the mansion, seldom visited by the family; now a conservatory is considered necessary for every house of any pretensions, and is attached to, greatly adorns, nay, frequently forms the most costly part of it—the chosen rendezvous of the family and its guests, the cool and leafy retreat from the ball-room, and the most enjoyable after-dinner lounge.

Then, again, the improvements in the appliances for Warming Horticultural Structures have kept pace with the improvements in their artistic embellishment. When our business was first established, the old hot-air flue was in vogue, the science of heating by hot water was comparatively unknown, and the system employed most primitive—each house being warmed by a separate boiler, thus causing an immense amount of labour and serious waste of fuel. The whole aspect of affairs, however, was completely altered by the introduction in 1848 of our "Weeks's Patent Upright Tubular Boiler," which is pronounced by eminent engineers to be "the" Boiler for heating by hot water, being superior in rapidity and power to any other, thus enabling whole Horticultural Establishments to be heated from one stokehole by one furnace. Not content with this success, but bent on making a perfect boiler, we have expended large sums in carrying out experiments on an extensive scale, and from time to time have effected various improvements, which render our "Weeks's Patent Upright Tubular Duplex Boiler," with Patent Fuel Economiser, unequalled. Upwards of 3000 of our Boiler are now in operation in various parts of the United Kingdom, heating Horticultural Establishments, Conservatories, Mansions, Public Offices and Institutions, Cathedrals, Churches, Manufactories, Banks, Prisons, Baths, Hospitals, Zoological Gardens, &c.—in some instances as much as 3 miles of piping being warmed from one stokehole. In conclusion, we beg to state that we still adhere to our old principle, that "the best is the cheapest in the end." All buildings erected by us are manufactured by skilled workmen from the best materials. Every Hot-water Apparatus is warranted to answer its intended purpose, and every "Duplex Boiler" fixed by us is guaranteed for ten years. Catalogues free on application to

J. WEEKS and Co., *King's Road, Chelsea, S.W.*

J. WEEKS & CO.'S ADDRESS.

SUPPLEMENT TO THE GARDENERS' CHRONICLE.

FRUIT CULTURE.

THE subject of Fruit Growing for the People has not yet received the attention that the importance of fruit as a cheap, wholesome, and pleasant article of food, claims for it. Thousands of small gardens are yet every year almost wholly cropped with Potatoes, and, unfortunately, this crop becomes almost every year more precarious. To depend on them alone is, therefore, as impolitic as it is likely to prove improvident. In fact, since

the first outbreak of disease, the *Gardeners' Chronicle* has ever been the earnest and persistent advocate of the cultivation of a larger variety of vegetables by cottagers, and, indeed, by all classes, in their gardens; and the advice thus wisely given has been largely taken and acted upon. One of the most marked and striking differences between the cottage gardens of to-day and those of a quarter of a century ago, consists in the greater variety and superior quality of the vegetables grown in them—a step in the right direction. Variety of food is not only good for sharpening appetite, which seldom fails the humble cottager, but it is necessary to health and promotion of simple pleasures,

The next great step forward in the culture of cottage gardens and small gardens generally will consist in the growth and consumption of more and better fruit. In most gardens may be found few or many trees or bushes, good, bad or indifferent, mostly the two last—and these have been allowed to remain, rather to the discouragement of fruit cultivation. The two rules as to the letting and holding of cottage property—conservative tastes in regard to trees, and even not seldom the love of picturesque forms—have combined their influences to preserve trees that bore little and showed much, and thus became and remain the bane of many cottage gardens. The planting or allowing to remain in small gardens inferior or worthless trees or bushes is one of the greatest losses to the cottager, and one which has created a strong prejudice against fruit culture in not a few of the rural population. This can only be broken down and removed by the planting of the finer varieties of fruits and trees of such sizes and characters as will yield the most fruit with the least encroachment upon and injury to the crops of vegetables. Good trees occupy less space, and need no further culture, skill, and care than bad ones, while the difference in their produce for sale or food is wide as the poles asunder. The smaller the garden the greater the necessity for the most rigorous selection. Those who have room

for a dozen, a score, fifty, or a hundred trees, can afford to grow inferior sorts; those who have room for only six or a dozen trees, cannot afford any but the very best. Much may also be gained by adapting the character of the trees to the size of the garden. In most of the older cottage gardens it matters not whether the trees are Apples, Pears, Plums, Cherries—all are of the same character, either tall standards or dwarf orchard trees. In the larger cottage gardens these trees answer well, and allow sufficient head-room for the growth of vegetables, or Gooseberries, Currants, and Raspberries, underneath them. And this double cropping of Apples or Pears above and bush fruit below, proves as practicable as it is profitable. Two, or it may be even three crops are gathered off the same ground, and the bush fruit are hardly injured by the shade of the trees over them, unless, indeed, the trees are planted too closely together. But these large trees are the bane of small cottage gardens, rendering the cultivation of superior vegetables impossible, and producing an amount of shade that is often fraught with danger to the health and comfort of the dwellers in the cottage. Nothing is more wholesome and sanitary than a well cultivated, fully furnished garden, fully exposed to sun and air; few things are more unwholesome than damp or dank ground near to dwelling-houses, the sun and air shut out from it by the shade of fruit or other trees; there-

FIG. 1.—ST. AUBERT PLUM.

fore on sanitary grounds, as well as with a view to profit, small pyramidal or bush fruit trees should be selected for the furnishing of small cottage gardens.

DUTIES OF LANDLORDS.

The selection and purchase of fruit trees and bushes, and the planting of them, should be done by the proprietors, under the direction of their gardeners; and failing the services of the latter, provincial horticultural societies could hardly render a higher service to society than by the advising of the owners of cottages as to the best character and varieties of fruit trees and bushes to plant in the garden.

As the law declares every permanent tree or bush found in the garden, no matter by whom planted, to be the absolute property of the owner of the soil, it follows that the landlord ought to provide and plant them. This is the more necessary, as most cottagers are only yearly tenants, and can hardly be expected to incur much expense in the purchasing of trees, and making the needful preparations for their well-doing for a lifetime or more perhaps. In not a few cottagers' gardens, for instance, the soil is of the worst possible description for the growth of fruit. It is generally an easy matter for a landlord, with horses and carts and capital at command, to substitute good soil for bad, or improve indifferent soil into good by some addition or admixture of earth or manure. But such matters are quite beyond the means of cottage tenants, and would, in fact, be the height of imprudence in the case of those who hold their gardens on the short and slender tenure of a month's notice to quit. Drainage, again, is another operation that ought to be performed by landlords. It is generally beyond the power of cottage tenants to deal effectually with an excess of water. Stagnant water at the roots of fruit trees and bushes is fatal to their successful cultivation. And there are few things more unkind or more unjust than to condemn a cottager to cultivate a garden of bad wet soil when it might easily have been laid dry and made good in the first instance at a trifling cost to the owner. It would be infinitely better to charge the cottager the interest on the capital expended in additional rent than condemn him to cast the time, labour, and skill of years into a veritable Slough of Despond compounded of inferior sorts of fruits, worthless and wet soil, that can yield little return but sour disappointment. It is alike the duty and interest of the owners of cottage gardens to remove all preventible hindrances to the extension and improvement of fruit culture by cottagers. It would be far better, more benevolent also, to give him a fair start in fruit culture, with good trees in good soil on dry bottoms, than to bestow on him a gift of flannel, coal, or a dole of meat at Christmas time.

There is one more service the owner should do for the occupiers of cottages, that is, to see that their houses and gardens are not overshadowed and under-rooted into comparative worthlessness by forest or other trees. The first garden the writer had anything to do with had one-third of its area reduced to sheer barrenness by the shade and exhaustion of a large round-headed Beech tree; and it is no uncommon thing to meet with cottage gardens half or wholly ruined by hedgerow or other timber. Such things happen for want of thought, and it is hoped that the mention of them here will be sufficient to remove them.

With a free soil, exposure to sun and air, and a dry bottom, most cottage gardens will grow good fruit trees and bushes. A good stiffish loam is the best soil for both, and little or much of this might often be added, at little cost or inconvenience; but good black garden earth, such as is produced by the long cropping and manuring of so many cottage gardens, is capital for bush fruits, all of which thrive best on fat land heavily manured with solid dung, and deluged with house slops or sewage in dry weather in summer.

THE TIME TO PLANT.

The whole month of November is the best time for planting fruit trees. Plant earlier—the fruit-buds for next year have hardly had time enough to be sufficiently developed; plant later—part of the most active season for the healing and resting of injured roots and the forming of new ones has already passed away. Strawberries, a very profitable crop for cottagers in many districts, should be planted in July or August, or as soon as well-rooted runners can be procured.

HOW TO PLANT.

First of all see that the holes are large enough, or, say, 6 inches wider than the sweep of the roots when laid out from the bole to the outside of the hole, like the spokes of a cart wheel from the nave to the felloes. The vital force or growing power of the roots lies in their extremities, and it is, therefore, of the utmost moment that they should find fresh soil to strike into at once. The depth of the holes may range from 4 inches to a foot. The larger the trees, and the more numerous the roots, the deeper, as a rule, the holes should be made. In the rebounding from deep planting not a few have run to the opposite extreme of placing the roots too close to the surface. Mulching, or the covering of the roots over with a layer of long litter or rotten dung, is but a clumsy substitute for the natural covering of soil, which should on no account be withheld from the roots. The holes should be made perfectly horizontal—neither concave nor convex. By raising the holes in the middle the feeding roots are apt to be sent too deep. By keeping the centre hollow the bole of the tree is placed in a hole, and the feeding roots need to run up-hill till they crop out on to the surface. The holes should be perfectly level, and made smooth and firm, so as to cause the roots to start fair for their food. The roots should also be evenly distributed, not huddled together in masses, but each placed so as to have or find a separate feeding place wholly to itself. Each bruised or wounded root should be carefully dressed to a smooth surface, or removed by a clean slanting cut. Either favours rapid and sound healing, or the emission of fresh roots. No tramping or mechanical pressure should be applied to the roots. Place the soil over them, the finest parts next to the roots; water it home if the earth or the weather are at all dry, and the weight of the wet earth and trees, the great consolidator, will do the rest with perfect safety and sufficient despatch, which is more than can be affirmed of any other mode of compressing the soil over or among the roots. Finally, in regard to planting, fix the tree or bush immovably to some support. One of the first functions of the roots of trees is to secure immobility of root and top; in other words, to fix them securely in one place. Derange that function by transplantation, and it is needful to provide a substitute in the form of ties and stakes for a time, until the roots lay fresh hold of the soil. A loose surface over the roots is also important in keeping out the cold of winter, conserving terrestrial heat, and resisting drought.

DISTANCE APART AND CHARACTER OF TREES TO PLANT.

It is impossible to separate these two, as the proper distance, while partly determined by soil and climate, chiefly resolves itself into a matter of character of trees planted. For example, 20 or 30 feet asunder may not be too much for standard fruit trees, while 1 foot or 18 inches is hardly too close for cordons. The introduction of these smaller forms of fruit trees into cottage gardens will be one of the greatest steps in advance that have yet been taken in fruit culture during the century. One may travel for weeks throughout the rural districts without meeting with a single form of fruit tree different from the dwarf and tall orchard tree; even pyramidal and bush trees are almost wholly unknown in farm or other gardens. By using smaller trees far more and better fruit might often be gathered from a smaller area. The concentration of force in fruit growing reaches its limit in upright or oblique cordons on walls or fences planted a foot apart. Small pyramidal or bush fruit trees may be planted from 3 to 6 feet apart; Apples and Plums in alternate rows, 5 feet apart, have been found a most profitable crop, the one tree sheltering the other. From 4 to 6 feet apart is perhaps the most profitable distances for pyramidal or bush fruit trees. These distances apply to Apples, Pears, Cherries, Plums—horizontal trees for the covering of outbuildings, fences, walls, espalier-rails or stakes in gardens, from 8 to 12 feet apart; Peaches, Nectarines, and Apricots, as fan-shaped, from 12 to 15, or 18 feet apart—standard and dwarf trees from 12 to 20 feet apart; Gooseberries and Currants in 4 feet rows and 3 feet from plant to plant; Raspberries in 4 or 5 feet rows, and 2 feet between the stools. There is often considerable loss of ground between the stools of Raspberries, and provided the rows are sufficiently far apart it will be found far more profitable to have the plants well-nigh meeting in the lines. Grape Vines in cottage gardens are generally grown of very large

size, sufficient to cover the side or end of a house. Much time may, however, be saved by planting Vines closer—at distances, say, of 2 feet or a yard, and only allowing each plant to cover a limited space. The same remark applies to Figs, which might often be grown to great advantage on the warm gable ends of cottages, and would prove a most profitable crop in many localities. The one-plant system, however, will probably prove the most profitable in the end, with Vines and Figs alike, only cottagers cannot always afford to wait, and, in fact, one man is very apt to plant and another to reap where fruit trees are planted too far asunder in cottage gardens.

STOCKS.

Without at all entering into the battle of the stocks here, it may be well to remark that they are closely connected with the question of the profitableness of fruit growing. Large or orchard Apples should be grafted on the Crab, all other sorts and forms of trees on the English Paradise stock. Pears for large trees may be worked on the wild or seedling Pear; for pyramids, bushes, cordons, on the Quince; dwarf and bush Cherries on the Mahaleb stock. The Myrobalans forms the best stock for Plums, and the smaller trees may be kept at once small and fruitful by being severely root-pruned, or taken up and re-planted every other year in November. In fact, all small fruit trees may be kept small and fertile by root-pruning, as we shall see. But if on rich soil and in warm forcing localities the trees grow so fast as to become overcrowded every other tree and row may be removed to fresh quarters, thus affording those left double the space to grow in, while the trees removed will form a new fruit garden at once; and, if this operation of thinning is performed early in November, with ordinary skill the thinnings will begin bearing at once and never look behind them.

PRUNING.

Newly planted trees should not be pruned till February. Established trees may be pruned any time in winter after the fall of the leaf till the active rise of the sap. But great changes have recently occurred as to the time, manner, and extent of pruning. Only a few years ago all newly planted trees were severely pruned as a matter of course. Heading back succeeded to planting as surely as night to day. Now cultivators prune or not, as the character of the trees and the objects of the grower suggest or require. Without going so far as to assert that all pruning represents a waste of time and force, and is the price paid for form and fertility by thoughtlessness, ignorance, or incompetence, it is now generally admitted that the less pruning the better alike for the tree and the cultivator. Still, while the innate tendency of trees or bushes is to climb as high as possible with but scant care for symmetry of form or fulness of furnishing of the bottoms of trees and plants, it will be needful in general to prune and cut away portions of the tops of new planted trees. This forces the lower buds to break, and these form the framework, as it were, of the future tree. With the base line of trees and bushes well and truly laid, Nature will be sure to take care of the full furnishing of the tops; hence the propriety of often cutting back newly planted young trees to within a few buds of their root-stocks. Then five, seven, or more shoots of about equal strength may then be produced, and trained, so as to form the future tree. This sort of pruning may be as philosophical as it is practically useful. In all plantings the roots suffer injury, diminution, and arrest of growth—of shorter or longer duration. They are more or less crippled, consequently are hardly able to sustain the entire top in health and vigour. By cutting back the top the balance between the two parts of the tree is restored, and healthful growth results as a matter of course; but, if the top is too severely cut back, the roots have not enough work to do, and the result is an excessive growth of wood. As fruitfulness is the primary object of planting fruit trees and bushes, one of the surest means of inducing and perpetuating it is to leave most of the top intact, so as to somewhat overtax the roots, for such a condition is the most favourable for fertility; therefore prune as little as possible, and only so far as is needful to insure good form. Top-pruning for fertility is a mistake; fruitfulness is reached far sooner and with more certainty by other methods, notably by shallow planting, root-pruning, and having all the tops of trees and bushes to grow fruit for puddings, pies, preserves,

instead of pruning them off into oven faggots, merely to bake or make such good things.

Winter-prune fruit trees for form only. It is needful to force growth at the best places, to reduce its amount at times, so as to prevent overcrowding, and to remove weak, worthless and diseased shoots. Beyond these objects, little winter pruning is necessary; and in regard to orchard trees, little or none are grown in cottage gardens.

SUMMER PRUNING.

Summer pruning is even less practised, but it is far more important. Many trees, such as Apples and Pears, often make enormous growths of young wood every year. Currants grow a crop almost as tall as Willows, and fit for basket-making. These smother the fruit and each other, and render the buds at their base thin, small and almost worthless for fruit bearing. At the winter pruning the majority of these shoots are started off, and there remains only the worst and weakest parts of them for fruiting the next season. Prune off the breastwood in July or August—the autumnal suns, rains, and dews, and the vital force of the plant will plump up the narrow buds before the end of the growing season. The light, heat, and moisture shut out by the crop of gross shoots before, will after such summer pruning play freely around and among the clusters of fruit-spurs most found around their base, and fill them to the brim with fruit in embryo. In a word, summer pruning, properly understood and practised, is simply placing fertile power where it will be found next year in a plentiful crop of luscious fruit (weather permitting), instead of permitting it to run to waste in the extremities of shoots, to be slashed off at the winter pruning.

ROOT PRUNING.

Supposing, however, that from faulty planting, excessive richness of soil, bad culture, or other causes, fruit trees and bushes yet decline their proper work, that of fruit-bearing, and take to wood-making instead, the cultivator has still another power at command that will compel fertility: this is root-pruning. It is needful, however, to caution cottage gardeners against practising it too often or annually. It is an exceptional operation performed for a specific purpose—the checking of wood-making and the forcing of fertility, and must on no account be confounded with the winter or summer pruning of the top. More or less of these may be needful every year, root-pruning may never be needed more than once in the life of an individual plant, perhaps not even once. The tendency of most cultivators—the more ignorant the stronger the tendency—is to do too much for or to the trees. An Apple, Pear, Plum, Cherry, or other tree is doing well, then let it alone, and by no means touch its roots. The best time to root-prune fruit trees is from the middle of October to the end of November. The mode of doing it is simple: uncover all the roots to a distance of from 5 to 6 feet from the bole of the tree, according to its size; cut all the vertical roots formed, as also a few of the strongest of the others, at a distance of a yard or so from the bole of the tree, and replace the soil.

TRAINING.

Trees should be started on the right tack at first, for "as the twig's bent the tree's inclined." If this is done but little after-training will be needful. The most common form for Apples in orchards is a sort of open centre or vase form. This admits the sun and air to all parts of the tree. The same form is well suited for Cherries and Plums; Pears are often allowed to grow up into a sort of rough pyramidal form with one leading and many subordinate shoots. The horizontal form is the most common for walls. The trees being cut back to two, four, or six buds, the branches produced from these are carried off at right angles from the bole and centre at distances from each other mathematically of from 9 inches to a foot. The fan system is also very generally adopted for walls and fences. In this form the two bottom branches are trained the same as with horizontal training, and the other branches proceed from the bole at equal distances, filling the entire space with fruit-bearing shoots disposed in the form of a fan, with generally more or less depression in the centre. A modification of this form may be strongly recommended for Figs, Cherries, Plums, and Apricots. Instead of pruning back the young and breastwood every year, the greater part of it is allowed to grow out from the walls, merely

thinning out the weakest and that of least use, to prevent overcrowding. After a few years the tree presents the appearance of a bush or pyramidal tree split in halves, and backed against the wall or house, the whole of the tree from base to summit being covered with fruit. One such roughly trained tree will often yield more fruit than half the neat and trim trees occupying six times the wall space. A modification of this free training also suits cordon stone fruits remarkably well. Instead of pinching and pruning in the young wood or spurs so closely, allow them more freedom, and Apricots, Plums, and even Peaches, will bear enormous quantities of fruit. Trees intended to be trained in this way should be planted further apart—from 30 inches to 3 feet, or even more. Gooseberries and Currants fruit profusely backed up against outbuildings or walls

FIG. 2.—GOOSEBERRY PRUNING.

in this way, and form capital screens to piggeries, closets, and other outbuildings—at once ornamental, profitable, and sanitary. This leads us by a natural transition to the

PLACE FOR PLANTING FRUIT IN COTTAGE GARDENS.

Briefly, as close to the houses as may be, and this for the double reason of safety and convenience. A great amount of fruit is often lost by birds and other causes, by the fruit being planted at the extremities of the garden. Each cottage, however small its garden, should have it laid out in a threefold zone, as it were—flowers and sweet and fragrant herbs and plants immediately around the house, next the fruit, and then the vegetables. Few birds care to come too close to a cottage door or window, even for a ripe Cherry or a bunch of Currants, while children may be trained to protect and not steal the fruit. Then, as many of the cottages and outbuildings as can be spared from Honeysuckles, Jasmynes, and Roses should be devoted

FIG. 3.—RASPBERRY TRAINING.

to fruit culture. A Grape Vine, a golden Apricot, a red-cheeked Peach, a black or yellow Plum, Cherries, Pears, Apples, are highly ornamental as well as useful. Plums may be led over low roofs, and so can Figs, Pears, or other fruits, to great profit at times. Ground cordons make beautiful edgings to walks, or even flower beds or borders, or partitions between neighbours' gardens. There is an enormous loss of ground by dividing lines of hedges, though posts or stakes, or a few strained wires for espalier Apple or Pear trees, would form an equally good fence, while the fruit would be a clear gain and more, for the fruit trees would exhaust the soil on either side far less than the useless hedges. There are few cottage gardens surrounded by walls; where these exist they should also be clothed with fruit trees and bushes. When all waste or unoccupied spaces were filled, the rows of dwarf trees might be planted on either side of walks or groups of them, or fruit gardens formed next to the flower beds, forming a connecting link

between the flowers and the vegetables. By grouping fruit trees and bushes in masses they would be far more easily protected from birds, rodents, and bipeds—points of much practical importance to cottagers: the trees would also receive more care and attention. Now in too many cottage gardens fruit trees and bushes are too often left to shift for themselves. Mass them under the eye, grow more and better fruit, and the very effort would improve while extending their cultivation.

WHAT TO GROW.

Apples for puddings, Pears for pies, stewing and eating; Plums and Cherries for tarts, dessert, and preserving; Gooseberries, Currants, Raspberries, Strawberries, Filberts, for eating and preserving; and in warm localities and on suitable soils, Grapes, Apricots, Peaches, Nectarines, and indeed all fruits, for sale. Cottagers who have gardens of considerable size might often pay their rent and buy their coals with their fruit. A good Apricot tree on the gable end of a house helped through fickle springs by the heat of the chimney, seldom misses a crop, and may be relied on to pay the rent of the cottage. And so in a degree with other trees. Cottagers have been known to pay their rent with a row or two of black Currants. But the money made by the sale of fruit out of cottage gardens is a most inadequate test of their value. No one can doubt that fruit is sanitary as well as nutritious. A plentiful supply of good fruit for the children probably keeps disease and the doctor out of thousands of cottages, helps fathers to win bread by day, and mothers to distribute it with industry and prudence to the satisfying of their households.

The social and moral influence of fruit growing and eating has yet to be weighed and written, and will be found to be wholly on the side of virtue and happiness.

OUR ILLUSTRATIONS.

THE group of Plums, so ably portrayed in colours by Mr. Fitch, and presented to our readers with this number, includes the varieties known as Coe's Golden Drop, Diamond, and Belle de Septembre. Of the first named what need be said to enhance its value? Is it not grown by well-nigh every gardener, amateur and professional? And has it not the character of being one of the most useful of September fruits either for the dessert or preserving? It was raised by Mr. Jervaise Coe, a market gardener at Bury St. Edmunds, about the end of the last century, and is now very widely cultivated. It is large in size, oval in shape, and pale yellow, dotted with red in colour. The flesh, which adheres to the stone very firmly, is of a pale reddish yellow colour, rich and delicious in flavour. The Diamond Plum is not so well-known as the first named, but it is none the less valuable for culinary purposes, ripening in the middle of September, and making an excellent preserve. It was raised at Brenchley, in Kent, some years ago, and is of large size, oval in form, with a well-marked suture, deepest near the stalk. Its colour is dark purple, nearly black, and the fruits are usually covered with a beautiful rich light blue bloom. The flesh, which also clings to the stone, is yellow in colour, with a sharp acid flavour. Belle de Septembre—also sometimes well called the Autumn Beauty—is perhaps the handsomest and most valuable of late varieties. It is the late Plum *par excellence*, coming into use at the end of September or beginning of October, when the glut of summer sorts is over, and realising good prices at market, for which purpose, on account of its fine size and taking appearance, it is exceedingly valuable. It is a roundish oval Plum, of a pale claret colour, which becomes of a deeper shade with age. It is a clingstone, has a very firm yellowish white flesh, juicy and aromatic, and in all respects is an admirable culinary variety, besides being a most prodigious bearer.

The St. Aubert Plum, so effectively illustrated on our front page, fig. 1, is but little, if at all, known in this country. It is of Belgian origin, and much resembles Coe's Golden Drop, but is said to ripen nearly a month earlier, and to be superior to it both in quality and productiveness. However that may be, it is a very handsome, and no doubt a good Plum. The illustration serves the double purpose of calling attention to the Plum itself, and of showing how effective a dish of fruit may be made to look with the aid of such simple materials as a spray or two of Ivy.

Of the Apples on p. 6, fig. 14, the first, Cox's Orange

Pippin, is certainly the very best of all in its season. From October to February Golden Noble (fig. 15) is a large, handsome, yellow, culinary Apple, in use from September to the end of the year. Perhaps of all culinary Apples the best and most useful is the Stirling Castle (p. 7, fig. 18), a very free bearer, and well adapted for bush culture on the Paradise stock. The fruits are of medium size, pale green in colour, and the flesh white and juicy. It comes into use in August. Reinette de Caux (fig. 19) is a French Apple, but little known in this country—but it is well worth growing on account of its valuable late-keeping qualities. It much resembles the old Dutch Mignonne, and comes into use late in spring, when good Apples are very scarce.

The Pear Van Mons' Léon le Clerc (p. 6, fig. 16) is a remarkably large, handsome, and delicious variety, ripe in November. Doyenné du Comice (fig. 17) is the finest of all the October Pears, being large in size, remarkably rich in flavour, and the tree a good bearer. Durandean (p. 7, fig. 20) is a very fine variety, of Belgian origin—being large in size, of handsome form, and very delicious flavour, comes into use about the

FIG. 4.—PLUM.

beginning of November. Beurré Hardy (fig. 21) is one of the best November Pears, though but little known. It is a beautiful and handsome fruit—of delicious flavour, but is not a great bearer.

The four varieties of nuts illustrated on p. 9 (fig. 22) are the Red-skinned Filbert, a free bearing and excellent flavoured variety, which produces its elliptic acute shaped nuts in clusters, and has a husk longer than the nut; Princess Royal, a comparatively new seedling, raised by the late Mr. R. Webb, in which the husk is as long as the nut, and the latter of fine size; the well-known Cosford, which fruits in pairs; and Empress Eugénie, another of Mr. Webb's fine seedlings, in which the husk is shorter than the nuts, which are borne in clusters.

PRUNING.

To be a good pruner requires instruction in the first instance from a practical man, and in the next place considerable experience, with sense enough to profit by it. The questions a would-be pruner should ask himself before using the knife are—Why am I going to do this violence to Nature? Will any good result? Will the advantages outweigh the disadvantages? Having settled these points, the next question will be, How am I to do it? The answer to

FIG. 5.—PEAR.

FIG. 6.—PEACH.

FIG. 3.—CHERRY.

FIG. 7.—GOOD AND BAD PRUNING.

this will again depend on circumstances—on the object to be attained, and on the kind of tree to be operated on, and its particular mode of growth. No doubt if all these questions were duly asked, and satisfactorily answered, there would be far less pruning carried out than there now is. Still some amount of pruning is often absolutely required—how much must be determined by the exigencies of each particular case, and the judgment of the operator. Pruning, not mutilation, is in all cases the object to be attained—conservative surgery, not reckless hacking. On the other hand, in considering the matter of pruning it, must be remembered that we are not so much consulting the welfare of the tree as our own advantage. No doubt the tree would prefer to be let alone, and to be allowed to grow in its own way, but we want it to occupy a certain position, to attain a certain height, to assume a certain form, and in the case of a fruit-tree to produce a fair share of fruit larger probably in proportion to the wood and leaves than the tree left to itself would form. Moreover we look for superior quality of fruit. To effect all these good things we

require a shapeable tree, with a fair proportion of fruit-bearing wood as contradistinguished from mere timber, therefore a tree with a proper balance between leaf and flower-shoots, and one wherein the flow of nourishment may take its even way in as regular proportion as possible to all parts of the tree alike. We don't want one branch to be gorged like a traditional alderman, while another is starved like a dock-labourer out of work. Moreover we want God's most precious gifts of light and air to penetrate all parts of the tree equally, or as nearly so as may be. These in very general terms are the principal objects of pruning. How to carry them out is, as we have said, an affair to be learnt from actual experience. No book, no newspaper article can teach this half so efficiently as a little practical experience under the guidance of an expert. In France, in Belgium, in Germany, such experts have classes for this purpose; the class gathers round the Professor, who prunes the tree and explains the reason why. As Jacques Bon Homme or M. le Curé cannot always conveniently pay a visit to Paris or Lyons, or wherever the Professor's headquarters may be, the Professor goes to them, in the small country towns. He tells his audience what to plant, where to plant, how to plant, how to manage, and how to prune. Practical matter-of-fact Englishmen don't do this. Some

FIG. 9.—GOOSEBERRY.

day, perhaps, when horticultural societies rise to a full sense of their duties, they will see that work of the character we have mentioned is, to say the least, as important as growing endless Pelargoniums and certificating illimitable bedding plants.

The accompanying illustrations will suffice to give a general idea of the natural growth of particular fruit trees and the form and arrangement of the buds. In the space at our disposal it is absolutely impossible to give full directions for pruning each tree, but a good deal may be learnt from a mere inspection of the figures, and for the rest let the amateur get some good knife-man to give him some lessons.

Good and Bad Pruning.—In pruning a clean cut

FIG. 11.—APPLE.

should invariably be made sloping downwards, at an angle of about 45° at the back of the bud, as at fig. 7, *a*, so that the wounded surface may speedily be healed over. At *b* the cut is too low down, as the bud will probably die; *c* is a cut which carries its own condemnation with it; *d*, *e*, *f*, are other modes of effecting the cut. In *e* and *f* it will be observed that the cut slopes up from the bud, and on the same side of the stem. As the portion between the cut surface and the bud will most probably die, it will be seen that all these methods are inferior to that shown at *a*.

Plum.—Fig. 4 shows portions of shoots, of one, two, and three years of age respectively; *a*, *a* are flower-buds, readily known by their rounded shape; *b* are wood-buds, which are of a more pointed form. The object of pruning in the case of the Plum is

FIG. 12.—CURRANT.

simply to equalise the size of the branches, preserve the form of the tree, and remove superfluous growths and "gross shoots," *i.e.*, shoots which would form too much wood.

Cherry (fig. 8).—The buds are very similar to those of the Plum, and, except in the Morellos, are borne at the base of last year's shoot. The objects of pruning are the same as in the case of the Plum.

Peaches and Nectarines (fig. 6) bear on the shoots of the previous year, hence in the winter pruning the

FIG. 10.—APRICOT.

FIG. 13.—RASPBERRY.

FIG 14.—COX'S ORANGE PIPPIN.

FIG 15.—GOLDEN NOBLE.

shoots formed in the preceding summer require to be cut back to the point where the wood is well ripened, as it is upon this ripened wood of the one-year-old shoots that the flower-buds are formed.

Pears.—The fruits are borne on thick stout spurs. The object of pruning and stopping is to secure the formation of the spurs by arresting undue luxuriance of growth. In fig. 5 *a*, *a* are wood-buds, *b* fruit-spurs, *c* the place whence the fruits of the preceding season have fallen.

Gooseberries.—The fruit-buds are formed principally, but not entirely, on two-year-old wood (fig. 9). The object of pruning is to shorten the shoots, to cut out the central branches so as to keep the centre open to prevent entangling of the branches (fig. 2), and to encourage those buds which are placed on the outer side of the branches.

Apricots.—In fig. 10 *a*, *a* are the flower-buds formed on the young wood and on short spurs. Little is required beyond shortening the shoots and regulating the form of the tree and the size of the shoots.

Currants.—A clean stem is here the object, and a

shortening of the lateral shoots. In fig. 12 *a* are wood, *b* fruit buds.

Raspberry.—The canes of the Raspberry are biennial—that is, they are produced one year, flower and fruit the next, and then die down, others having been formed meanwhile to replace those that die. All that is required is to cut away all dead wood and shorten and thin out the growing canes. A convenient way of training them is shown in fig. 3.

Apples bear on two-year-old spurs (fig. 11). Little or no pruning is required beyond regulating the form of the tree, the number and arrangement of the branches. Branches that cross one another should be cut away as well as those that are cankered.

THE APPLE.

THE Apple has for many centuries been the fruit most intimately connected with the daily household life of all the northern European nations, it is the one

fruit altogether and entirely indispensable, no table can be properly served without its appearance, if not daily at least on so many days that its absence is almost as much deplored as bread, if not by the elders at least by the younger members of the community; and what boy, where Apple orchards are numerous, has not his pockets full? I have heard of some boys in Worcestershire who acknowledged to having consumed twenty full-sized Codlins per diem, besides Apple puddings, Apple turnovers, Apple fritters, not to speak of such evanescent trifles as Apple jellies. And what a treat round the hearth is an Apple roasting on a piece of worsted, hissing and bursting with the imprisoned essences, to pass into the expectant mouth of the anxious watcher—a humble pleasure, but at least as great as that of the *blasé* wine-bibber, waiting the out-pouring of the best brand of Clicquot or Lafitte. And what fruit is more classical? Atalanta could not resist the golden Apples; Paris, bent on his own destruction, but deceived by the glamour of eyes ablaze

FIG 16.—VAN MONS LEON LE CLERC.

FIG 17.—DOYENNÉ DU COMICE.

FIG. 18.—STIRLING CASTLE.

FIG. 19.—REINETTE DE CAUX.

with love, handed an Apple to the object of his choice. We know that Adam could not resist the temptation of eating one, and from the time of Adam to the present no fruit has given so much pleasure both to the eye and palate. "From the egg to the Apple," a common Roman saying, proves that no Roman dinner was complete without it. In England, in remote times, it was surrounded with mysterious rites. The Druids, ancient and respectable gentlemen as they were, full of reverence for trees, were as respectful to the Apple as to the Oak; and it is not so long since that in the West of England the rude farmers and ruder peasants testified their appreciation of its good qualities by composing songs in its honour:—

"Here's to thee, old Apple tree!
 Whence thou may'st bud and whence thou may'st blow,
 And whence thou may'st bear Apples enow,
 Hats full, caps full,
 Bushels and sacks full.
 Huzza!"

is a verse of old Devonshire doggrel, to ensure the good offices of the guardian spirit of the orchards, descended probably from the time when the worship of Thor and Odin kept alive the spirit of a religion that was probably once pure but corrupted by the artifices of those who saw their profit in fastening the bonds of superstition on the ignorant and uneducated. Our Norman ancestors were either the introducers or adopters on a large scale of the Apple, as the province of Normandy to this day is the most important seat of its culture in France, and the Norman farmers on market days delight in a carouse of Cider brandy, cheap and heady, but of which they will consume quantities enough to make Sir Wilfrid Lawson more garrulous than usual and put his pet theories in his pocket for all time—keen hands at a bargain, but after business equally keen at drinking, beginning a sitting in the morning at 10 A.M., and concluding when it is time to return, *i.e.*, when darkness comes. Cannot Sir Wilfrid go to Caën for a season and endeavour to per-

suade the "gros Norman," to adopt his principles? Here is a chance of a "Crusade," such as seldom happens now-a-days; Crusader-like, however, Sir Wilfrid must be clad in triple brass ere he ventures to do battle with the Norman farmer or his spouse, with "No drinking of cider brandy" as a battle flag. Hearty men and good farmers are these cider growers, and their province is a paradise for the Apple and the Pear. One of the most delicious Pears bails from Avranches, and is well named the Louise Bonne d'Avranches, a title pirated by the Jersey men (more Norman than Normandy) as the Louise Bonne de Jersey.

THE PARADISE STOCK.

Fruitful as are the Norman orchards, the inhabitants by no means content themselves with the fruit from the standards, but most gardens contain garden trees on the Paradise stock, and this example may be successfully imitated here by the possessors of a garden

FIG. 20.—DURANDEAU.

FIG. 21.—BEURRÉ HARDY.

limited by yards instead of acres. On these trees fruit may be grown very superior to that on the standard trees, however fine; it is necessary to choose the sorts, and to be sure that the trees are grafted on the right stock. The Doucin is grown in large quantities in France, for this method of culture gives an intermediate growth between the Crab and the true Pommier de Paradis. The latter is very dwarf, and hardly fit for general culture, but the Doucin, like its superior cousins, the Monarch and broad-leaved Paradise, imparts a healthy growth, quite sufficient for a garden tree, although not strong enough for orchards. Grown into pyramids about 8 or 10 feet high, they are when fruitful exceedingly handsome trees. To keep up a healthy action combined with productiveness a circular trench should be made round the tree, increasing in diameter with successive years, and the trench filled with the favourite food of all fruit trees, good well-rotted manure, the said trench being renewed every second year, a surface dressing of the same material being applied every year. In June the first summer pruning must be practised, which consists merely in shortening the side branches, leaving the leaders untouched. Shorten these about the end of August, thin out branches to let in light and sun while the tree is growing thriftily, and the most important summer pruning is completed, keep the tree always symmetrical whether grown as a pyramid or bush. The culture is so simple, that no reason exists to prevent every cottage garden in England growing Apples on the Paradise stock. Standards take up too much room in a small garden, and, although immensely productive, must have been planted by a grandsire. In riding about my own district I have been struck by the appearance of some cottage gardens containing pyramid trees, and have been much gratified at the results obtained.

The careful cultivator must of course be careful in the selection of the sorts. Now I do not think it necessary to plant many kinds. The Red Juneating, Kerry Pippin, Devonshire Quarrenden, Early Harvest, Duchess of Oldenburg, Mother Apple, Irish Peach, Red Astrachan, will furnish a table until October; and for the kitchen, Lord Suffield, Keswick Codlin, Manks' Codlin (charming pyramid), Cox's Pomona, Hawthorden. After October Cox's Orange need be the only sort grown; it will keep good until February, and is peerless in its season. For stronger teeth the Ribston and Blenheim Orange will always hold their rank. There is much choice in winter Apples for the table; I believe no one will object to Brownlee's Russet, Duke of Devonshire, Scarlet Golden Pippin, larger and as rich as the old sort. All the Nonpareils are good; of the Pearmain, Mannington's, Adams', Claygate are not surpassed by any, and in the last days of winter, when the returning spring is anxiously expected, some Apples are still improving in quality. Of the late Apples, Lord Burleigh, Allen's Everlasting, Spring Ribston, or D'Arcy Spice Apple, Sturmer Pippin, are the best for keeping and flavour. For the kitchen, Dumelow's Seedling, Rymer, Tower of Glamis, Winter Hawthorden, Gooseberry Apple, Northern Greening, Striped Beaufin, will afford a pudding until the green leaves come again.

Several varieties of so-called Paradise stocks have been cultivated, but I think that two kinds raised here are the best for English soils and climate. These are the Nonsuch and the broad-leaved. The latter makes a more vigorous tree than the former, and is a good stock for the prolific sorts, such as Lord Suffield, Manks' Codlin, and others; but the former imparts a high colour to the fruit, and emits roots very freely. A correspondent in Scotland tells me that it is the best stock he has.

I shall be glad if owners of cottages can be induced to encourage their tenants in the cultivation of dwarf Apple trees by making them a present of a few trees. With patience and skill all districts and all soils will produce a reward, and a certainty of winning prizes at local shows (the most interesting of all shows).
T. Francis Rivers.

THE BEST SORTS OF FRUITS FOR COTTAGE AND VILLA GARDENS.

APPLES.

Dessert.—Kerry Pippin, Cox's Orange Pippin, Scarlet Nonpareil, King of the Pippins, Rosemary Russet, Braddick's Nonpareil.

Kitchen.—Lord Suffield, Stirling Castle, Blenheim Orange, Cellini, Warner's King, Dumelow's Seedling.

The best and most useful half-dozen:—

Dessert.—Cox's Orange Pippin, Scarlet Nonpareil, King of the Pippins.

Kitchen.—Lord Suffield, Stirling Castle, Blenheim Orange.

If two trees only are wanted, plant Cox's Orange for dessert, and Stirling Castle for kitchen.

If only one tree is wanted, we should plant Cox's Orange Pippin in preference to any other.

PEARS.

The best half-dozen:—Williams' Bon Chrétien, Louise Bonne of Jersey, Marie Louise, Beurré Bose, Glou Morceau, Winter Nelis.

Stewing Pear.—Uvedale's St. Germain. Any Pear will stew if used before it becomes mellow. It is therefore a waste of space to grow any for that special purpose, except it may be one monster variety.

PLUMS.

Dessert.—Six varieties:—Jefferson's, Kirke's, Green Gage, Transparent Gage, Violette Hâtive, Coe's Golden Drop.

Kitchen.—Six varieties:—Early Prolific, Victoria, Prince of Wales, Prince Engelbert or Mitchelson's, Belle de Septembre, Autumn Compôte. If only one is wanted for a wall, plant Victoria; for a standard, Mitchelson's.

CHERRIES.

May Duke, Black Circassian, Elton, Governor Wood, Bigarrean Napoleon, Morello.

PEACHES.

For House—Hale's Early, Stirling Castle, Noblesse, Walburton's Admirable.

For Open Wall.—Hale's Early, Grosse Mignonne, Bellegarde, Barrington.

NECTARINES.

Violette Hâtive or Elruge, Pine-apple, Lord Napier, Victoria.

For Open Wall.—Violette Hâtive, Lord Napier; the last for choice if only one sort is wanted.

APRICOTS.

Moorpark, or Peach.

FIGS.

Brown Turkey and White Marseilles.

GOOSEBERRIES.

For Eating or Sale.—Early Green Hairy, Red Champagne, Roseberry, Sulphur Yellow, Whitesmith, Gretna Green, Pitmaston Green Gage, Monarch, Red Warrington, Green Overall.

CURRENTS.

Red.—Cherry, Red Dutch. *White.*—White Dutch. *Black.*—Black Naples.

RASPBERRIES.

Fastolf and Yellow Antwerp.

STRAWBERRIES.

Vicomtesse Héricart de Thury, Sir J. Paxton, President, Sir C. Napier, Dr. Hogg, and Elton. If only one sort can be grown it should be Vicomtesse Héricart de Thury.

NUTS.

Cosford, or Kentish Cob; red or white Filbert.

WALNUTS.

Thin-shelled, or Dwarf Prolific.

GRAPES.

Open Wall.—Royal Muscadine, Black Hamburg. *Vinery.*—Black Hamburg, Madresfield Court, Lady Downe's, Foster's Seedling, Muscat of Alexandria. *For an Amateur's Vinery.*—Black Hamburg and Royal Muscadine.

THE HISTORY OF THE PLUM.

THE original parent of the numerous and various kinds of Plums with which our orchards are in good seasons better than the present stocked, and our market overflowing, is, without much doubt, the *Prunus domestica* of Linnaeus—a tree which "is believed to occur in a truly wild state in Greece, the south-eastern shores of the Black Sea (Lazistan), the Caucasus, and the Elbruz range in Northern Persia, from some of which countries it was introduced into Europe long before the Christian era." It is impossible to state with anything like precision the actual date of the origin of any of the almost endless forms of Plums which are now common in our orchards, nor is it indeed possible to say when or by whom many of them were introduced. Gerard tells us that he himself had

"three score sorts" in his garden, "and all strange or rare;" and he mentions "the grounds of Master Vincent Pointer, of Twickenham," as the place where "the greatest varieties of these rare Plums" were to be found. Parkinson also enumerates sixty sorts fit for an orchard, all of which, he says, are to be had of his "very good friend, Master John Tradescante, who hath wonderfully laboured to obtain all the rarest fruits he can hear of in any place of Christendane, Turkey—yea, or the whole world." Among these are a few with curious names, such as the Perdigrin, or Perdigwena as it is called by Hakluyt in 1582, who says it was procured "out of Italy with two other sorts by the Lord Cromwell after his travel." Then there is the Bowle, which is "flat and round, yet flatter one side, whence the name;" the Margate, which is unfavourably characterised as "the worst of an hundred;" the Prunecola, "small, white, of a fine tart taste," which is "brought over in small round boxes, and sold at the comfit-makers cut in twain, the stone cast away, at a very dear rate," of which more anon, and three or four sorts of Bullace are also mentioned. Miller gives only thirty kinds, but these are defined with some care, and are really distinct forms. We find among them most of those which are still familiar in our markets—as for example the Magnum Bonum (which he calls Bonum Magnum), the Egg Plum, and the Orleans (which our London costers have corrupted into "Arline") Plum; this last he says "is a very plentiful bearer, which has occasioned its being so generally planted by those persons who supply the markets with fruit: but it is an indifferent Plum; it is said to have been brought over when the English were in possession of Orleans in the time of Henry V." The Damson appears as the "Damask Plum," at least so we are inclined to believe, though Martyn takes a different view, for he mentions the "Damascene, vulgarly Damson," among the sorts omitted by Miller. The French Damas or Damask Plum is rather larger and rounder than the English Damson, and of a sweeter taste; it splits readily, and its flesh separates easily from the stone.

One of the most deservedly popular of Plums is that known as the Green Gage—a name of which the origin is probably known to but few of those who are in the habit of using it. The French call this Plum *La Reine Claude*, in honour of the queen of Francis I., during whose reign the tree was raised, or, as some say, by whom it was brought into France. This Plum is usually supposed to have been introduced with others from the monastery of the Grande Chartreuse to the garden of Hengrave Hall, Sussex, the seat of the Gage family, some time during the last century; but having been sent without a name, or the label having been lost, the gardener, to distinguish it, named it the Green Gage, in allusion to its colour and to the family who employed him; and by this title it has been since known. A writer in *Notes and Queries* gives a slightly different account of its introduction, attributing this to a Catholic priest, the Rev. John Gage, who resided in a conventual establishment abroad, and on one occasion brought over grafts of it to his brother at Hargrave Hall. By some botanists—Karl Koch, for example—the Green Gage is regarded as a distinct variable species, native of the Caucasus.

The Prunes, which are employed in medicine as forming an ingredient in the *Confectio Sennae*, better known, perhaps, as "Lenitive Electuary," are yielded by a variety of *Prunus domestica* known as P. Juliana, the "Prunier de St. Julien" of French writers. This form of Plum tree is largely grown in the valley of the Loire, especially about Bourgniel, a small town between Tours and Angers. The Prunes sold by grocers, and often stewed and sweetened for home use as a laxative, are yielded by the same variety. The Plums are dried partly by the heat of a fire and partly in the open air, being alternately exposed to one and the other, and are too familiar to need description. Prunes were at one time employed in the manufacture of the rather complicated dish called plum-broth, for the making of which full particulars are given in *The Queen's Royal Cookery*, published in 1713. "Two pound of stew'd Prunes," forced through a cullender, leaving the stones and skins; and 3lb. more, "well stewed" and boiled, were among the ingredients of this "dainty dish," and when quite ready it was to be garnished with more stewed Prunes. Loudon says the Plum known as the Perdigrin Blanc is that generally used in France in the preparation of Prunes. It is a long narrow

fruit, greenish white tinged with red, with rather a leathery skin and much bloom. "The flesh is greenish, melting, and so sweet as to have nearly the same flavour when eaten ripe from the tree as when preserved." What are called in England "French Plums" are mainly produced by a kind called the Prune d'As, which has a tough, deep violet skin, and is prepared in the same way as Prunes. The bloom upon them is sometimes obtained by means of indigo. The best kind of French Plum, however, is that prepared from the kind known as the Brignole. These are large yellow Plums, also from Provence, which are shaken from the trees when quite ripe upon cloths spread to receive them, and next day carefully skinned. This operation performed they are exposed to the sun for some days, and then impaled upon pointed osier sticks, when they are again placed in dry warmth and air for several days. The stones are then removed, they are pressed into a round form, and eventually placed in the daintily arranged little round Willow boxes in which they make their appearance among us.

tute for French Prunes when the latter are scarce ; it is a rather larger and longer Plum, with a somewhat thicker skin. On the banks of the Rhine, in Wurtemberg, Roumania, and several French provinces, a kind of brandy is distilled from Plums, and vast quantities of the fruit are absorbed in the maintenance of this industry. The beverage, which is said to be of some value as a tonic, is intermediate between Cherry brandy and brandy made from cider ; it is strengthened by the addition of Bullaces when in the cask.

Various good kinds of Plum have been raised in the United States, the Washington being perhaps the best of them. It is a handsome tree, with large glossy broad leaves and roundish oval deep yellow fruits, which are about 2½ inches in diameter. The discovery of its good qualities was due to an accident. It had been merely used as a stock on a farm near New York, but a sucker from it was sold to a Mr. Balmer, which came into bearing in 1818, and soon attracted attention. Once known, it was not long in attaining the high position which it still retains. An

greater light and dryness in the cottage are advantageous to the tenant, and those who have the superintendence of cottage property know the trouble saved by substituting trained trees for wild growths constantly requiring to be cleared out of the slates and pipes.

Well-chosen, and properly planted to start with, fruit trees will bear for years, and there is no reason that they should ever be allowed to grow into the unmanageable masses of foliage too often seen with gnarled trunks close down on the ground, choking all below, and only fruiting themselves on the upper surface.

Light and air are needed for the crop below, but light and air are as much needed amongst the branches and beneath them, as well as above, to insure a good crop on the tree itself ; and if the trees are chosen with branches starting at a good distance from the ground, and afterwards properly thinned so as to allow sunshine and air to pass among the boughs, the tree will bear all over instead of only above, and the ground below will be serviceable. Espaliers

FIG 22.—1, RED-SKINNED FILBERT. 2, PRINCESS ROYAL. 3, COSFORD. 4, EMPRESS EUGÉNIE.

It will have been observed, from what has been stated, that Provence is one of the chief Plum-producing districts of France ; and this has been the case from an early date. For a long period Plums enjoyed the exclusive privilege of the sale of Plums in the North of France ; those of the south-west provinces were sent, by way of Bordeaux, to England and the colonies, while those of Provence went to Germany, by way of Switzerland. The Plums of Tours enjoyed a great reputation even at Paris, which, however, is now lost ; and a French poet writes of that town :—

"Tours, ville que rendent célèbre,
Son archevêque et ses pruneaux."

It is stated that about half the Plums prepared in France are for home consumption, the remainder being exported to England, Russia, Holland, and America, which last country absorbs a very large quantity.

A German Plum—the Zwetschen or Quetschen—is widely cultivated in Germany for its fruit, which is used in a dried state as an article of food. It is, indeed, usually grown with a view to its employment in a dried form, and is a particularly hardy and free-bearing kind. It is sometimes imported as a substi-

article in our columns, 1876, vol. vi., n. s., p. 69, gives some account of the Plums in Servia and Bosnia, which may also be read with interest at the present time. *B. M.*

COTTAGER'S FRUIT TREES.

FRUIT trees in the cottage garden give such a comfortable addition to the income of the tenant, with little comparative outlay or trouble, that it is a pity more attention is not bestowed on the subject in some of our rural districts. Much more available space could be gained whether for vegetables or small fruits by keeping the standard trees properly open and clear from the ground, espaliers might be much more introduced, and the walls of the cottage utilised for tender fruit more than is generally the case.

They may not have the picturesque charm of Roses clustering round the door, or Vines (which can hardly under the circumstances be described as fruit trees) mantling roof and water-pipes, and every place where they should or should not be in their folds ; but they have beauty both in flower and fruit, and the trimness of the branches in winter is satisfactory in every point of view. The immediate money return and the

might be much more introduced for choicer fruits (Pears especially) which it may be desirable to keep under the eye. Planted about 2½ feet from the paths, their shade is not enough to be injurious. They give a trim edging to the beds, and the fruit can be hand-picked as it ripens, instead of being bruised beyond marketable value in falling from the tree. With the help of the cottage wall, there is no reason why almost all common kinds of outdoor fruit should not be cultivated by the cottager. Not quite all, for Peaches and Nectarines, except in very favourable situations, would usually require more reflected heat than is given by the short length of unenclosed wall, and they are also too conspicuous to be a safe crop.

Apricots are very desirable, so are the large yellow Plums and early or autumn Pears ; but the point to be considered economically is—what kind of fruit is in season at the time of the chief fruit demand of the neighbourhood. The influx of tourists brings a certain sale, and the presence of schools, time of visiting or return of families from London with regard to dessert fruit, and supplies required for jam with regard to the small fruit, all affect the selection ; but the choicer the fruit (so long as its culture is not beyond

the cottager's powers) so much more will be his return for the care bestowed.

With regard to the sorts horticulturally, it is best to find what kinds answer on the same exposure in the immediate neighbourhood, taking what bear outside the garden walls in the vicinity rather than those inside, as the reflected heat gives a much higher temperature than can be had on the exposed cottage wall.

It is easy by running the eye down lists in any gardening book to find good kinds—as, in Pears, the Jargonelle, Williams' Bon Chrétien, Louise Bonne, and many others, are excellent—but a little difference in soil and situation may make much in the crop; and if sorts are chosen known to do well in the neighbourhood, it saves a deal of disappointment.

This is the point where the cottager really needs help. He has probably little idea how to select his trees or to procure them, and assistance here is a solid kindness. He is often quite able to purchase them, but has no means of ordering them, and if the gardener of the landowner, or any one who takes an interest in the subject, will add the trees to their own order, and let the purchaser pay his part of the account to them, it will often make the difference of his having proper trees instead of the superannuated or worthless things which only cumber the ground.

Where the man cannot afford the purchase money local prizes are a good way of meeting the difficulty, and especially appropriate to village horticultural societies, or (as in this case the need once supplied is not likely to need repetition) an occasional gift would not come under the common objections to such methods of supply, and would at once be highly useful and most thankfully received.

With regard to planting materials there ought not to be much difficulty. In rural neighbourhoods there is generally plenty of old mortar, brick rubbish, and decayed leaf-mould to be had one way or other—often for gathering, almost always by asking; and (by collecting beforehand) enough manure may have been gathered off the roads, and (with stray bits of turf) enough may easily be got together to do without further assistance. The point is to have a good hole dug, the materials well mixed, and the tree planted at a proper depth, with its roots spread, then properly covered and firmly trod in, and of all things it should be set and kept upright. Half the waste of room in cottage gardens is from trees being allowed to slant in all directions, till at last the trunks may be seen fairly along the ground, all nettles and weeds below, and very probably nothing in the way of a crop on the one-sided head above.

It is well to protect the stems of the wall fruit against the cottage with a good bunch of Brambles, first to keep the young children who sit mostly at the cottage door from scraping the bark off with any odd thing that comes to hand, and afterwards to keep the older ones from climbing to pilfer the fruit, and the spot should also be chosen where it is not customary either to empty burning ashes or the collective slops from indoors. The liquids may do a deal of good if properly applied, but not whirled out of a pail with a good sweep at one spot daily—the ground affected becomes merely an impervious mass, and a young tree perishes almost as surely under this treatment as under the exhausted ashes hot from the oven. Also it is a great preservative to have a few short posts driven in near the door to hang pots (or anything which domestic convenience suggests should be hung outside the door temporarily) properly and avowedly on; no tree or bush can be expected to thrive if its stronger spurs are turned into kitchen pegs, or its head wrapped up perpetually in some portion of the wash (or at least the dish-cloth laid nicely out to dry on the top) as is so often to be seen, and unless some equally convenient arrangement is made there the things will be.

If nothing else can be grown on the cottage wall it might at least be utilised for red and white Currants, which bear excellently so placed, with little risk to the crop, and may be profitably planted against all the low walls and wooden palings of the cottage garden. Generally speaking, there is the greatest possible difficulty in growing the smaller fruits where the children have an excuse for passing near them. They vanish piecemeal, imperceptibly, and cause nothing but pain and vexation, being preferred apparently green; but on the damper walls, or in any spare corners clear of the regular traffic, black Currants are most desirable. Probably nothing brings in so sure a return as fruit-growing for preserving. There is, then, no difficulty about the fruit

being in exact order to a certain day, and a deal that would be unsaleable from rough usage answers perfectly well for the preserve pot. Families round are usually very glad of the supply; but if the cottager's wife could be induced to study the very simple details of the subject a large profit might be made by preserving on the spot.

Quantities of fruit may be saved in this way, for when the injured or decayed portion which would ruin the fruit before it could be sold is cut off, the rest is in perfect order, and the very richest and best preserve or jam is that thus made from small quantities of fruit taken as they occur every two or three days, so as to secure them at their prime.

The cottager has usually no convenience for storing fruit, and (simply for home consumption) the requisite flour, sugar, &c., needed to turn it into an article of diet make it too expensive to be of service to him; but for sale it may be made of far more benefit than he usually imagines, if he will utilise his ground by allowing air and light to pass amongst and under his trees in the way shown to be, not only possible, but profitable in the fruit-growing districts round London, and also by considering the neighbouring demand.

It is seldom the *bona fide* rural cottager can grow profitably for distant markets, as he cannot pack properly himself, and makes much less profit by selling to dealers than the neighbouring gentry; but with a little care in finding a purchaser before his fruit is dropping from the tree, and trustworthiness in fulfilling his orders, his fruit trees will give him a comfortable yearly profit on scarcely any but the original outlay and a little labour. O.

STRAWBERRIES.

MUCH has been written upon the cultivation of this most generally esteemed fruit. The writers who treat upon it usually start off with the injunction that Strawberries require a strong holding soil in which to grow them, and do not succeed in such as is of a light nature. This is not very encouraging to beginners in their cultivation who happen to live in neighbourhoods where the land is of a light description, of which a considerable portion of the kingdom consists. I often hear amateurs so situated say—"Oh, it is no use attempting to grow Strawberries on my light soil: I tried and failed;" or, "They grew and bore for a time whilst the garden was new, but after a few years the land gradually got so light that they would not do in it." My reply has generally been an interrogation, asking if anything has been done to try to induce them to succeed. The answer has almost invariably been much the same—"That plenty of manure has been applied to the soil, with no better results." At which I have not expressed the least surprise, but the reverse, as the manure in most cases would only aggravate the evil by making the land lighter, causing a greater disappointment in the plants running to leaf instead of producing fruit. Instead of using manure alone a dressing of marl or clay, about 3 inches in thickness, should be laid on the surface of the ground, which must be previously dug, and when it has got well dried by exposure to the sun and air the first heavy shower will reduce it to a pulverised state. It should then be pointed-in, mixing it with some 6 inches of the top soil, when, if the land is deficient in manure, some can be worked-in at the same time. After this let the whole be well trodden until it is quite solid, and plant as early in August as runners can be obtained. On land of this description the plants will not last as long as where it is of a heavier character, and naturally better adapted to the requirements of Strawberries; two years is long enough to let them remain. Instead of putting the plants in the usual distance of some 2 or 2½ feet betwixt the rows, and about half as much between the plants in the rows, I should advise their being planted much closer, say 14 inches betwixt the rows, and 9 inches from plant to plant in the row. In this way a great deal more fruit will be obtained the first season. As soon as this is gathered, every other row, and each alternate plant in the rows left, should be cut out with the hoe, leaving those remaining to stand another year, when they may be destroyed, and their place supplied by others planted on ground similarly treated, putting in as many each year as required to keep up the supply. By following this method on light sands, loam, and also on peaty soil that had both been long used as a kitchen garden,

and as ill-adapted for Strawberry culture as they well could be, I have been able to grow as fine fruit, and also secure crops regularly equal in quantity to what is usually obtained from land naturally better suited to their cultivation. At first sight some people might suppose that to carry out the details here mentioned would involve considerable labour and expense, yet this is by no means the case; clay can in most places be had at little cost, the extra labour is very little, and it must be borne in mind that light land, such as that under consideration, is very much benefited for succeeding crops of all kinds by being so treated.

The varieties of Strawberries have, like many other things of late years, so much increased as to make it perplexing what to grow. Many kinds are more variable in their adaptability to any particular locality than is the case with any other fruit we grow, yet there are some sorts that combine a free bearing disposition, good quality of fruit, with ability to do well in most soils. It is much better, especially in localities where the soil is not naturally suited to the growth of Strawberries, not to plant delicate growers or doubtful bearers.

For the guidance of those who have not had an opportunity of testing the merits of the leading kinds, I append the names of a few that will afford a succession, and which may be relied upon for giving satisfaction where Strawberries can be grown at all:—

Keens' Seedling.—An old, fine flavoured, free-bearing sort, and although not quite the earliest in cultivation, still, taking all properties into account, the best to depend on for first crop.

Sir Joseph Paxton.—A very free-bearing, early kind, and a good grower.

President (Green).—An immense bearer, of good flavour.

Sir Charles Napier will bear well where most others fail; a heavy cropper, fruit large.

Eleanor (Myatt).—Late; a good size, and free.

Elton Pine.—An old, very late variety, that succeeds where many fail.

Where the soil naturally is of a character adapted to the growth of Strawberries, I should substitute other kinds for at least two of the above, but where it requires especial preparation to get them to answer these are what I should plant. Z.

BEARING YEARS OF ORCHARDS.—The Michigan Pomological Society, says the *New York Tribune*, lately discussed the practicability of changing the bearing year of an orchard, so as to have it produce when orchards in general fail, and when prices are high. Examples were given of successful practice in this way by suppressing excess of production in the year of general bearing, and by feeding the trees well and keeping the head judiciously open to light and air. But of course the trouble is considerable, as is always the case when a rare object is aimed for. And only in sections like the east shore of Lake Michigan, where the blossoms are safe from climatic severities almost every year, is it worth while to attempt to change habits induced by natural causes. But it is always profitable to reduce excessive cropping. Very often one season by no means suffices to enable an Apple or Pear tree to recover from the exhaustion induced by a heavy crop, and to store up material and arrange it for another. Late sorts, which require the entire season to attain maturity, of course exhaust a tree more than those which fall from a tree early in August, and leave the tree two summer months of growth for recuperation. And it is consequently the winter sorts that are most prostrated by a heavy crop. In the discussion referred to, Professor Beale and Mr. Garfield cited cases in which they had observed that blossoms fertilised by pollen from other trees, in some experiments on crossing, yielded fruit as a result of this mere pollen-contact when others were generally barren. This agrees, as far as it goes, with the results observed by Dr. Gray, Mr. Darwin, and others as to the very much stronger growth of seedling plants from seed produced by cross-fertilisation. In an orchard under the writer's eye in August, 1877, there are scarcely any Apples on any trees where the whole head is of one kind, and a whole block of one sort. But there are scattering Apples on most of the specimen trees which have several different sorts grafted upon one head. Not enough, however, to be called a crop upon any one. They all bore heavily last year.

For numerous additional articles on fruit and fruit culture, including the Gooseberry, Apple, and the mode of constructing and managing orchard-houses, the reader is referred to the Number issued with the present Supplement.

KENTISH FRUIT TREES, ROSES, &c.

THOS. BUNYARD & SONS

Will be happy to forward their DESCRIPTIVE LIST of the above on application, and refer intending Purchasers to the notice of their Nurseries in the *Journal of Horticulture*, December 4, 1873, pp. 442 and 443.

The Fruit Tree List contains all Particulars as to

- | | |
|---|---|
| APPLES, APRICOTS,
BARBERRIES,
CHERRIES, CRABS,
CURRANTS, FIGS,
COB NUTS, KENT FILBERTS,
GOOSEBERRIES,
MEDLARS,
MULBERRIES, | PEACHES (RIVERS' NEW),
PLUMS,
NECTARINES,
PEARS, QUINCES,
RASPBERRIES,
VINES, RHUBARB,
STRAWBERRIES,
WALNUTS, ORANGES. |
|---|---|

The Trees, which are in the finest health and condition, and move with plentiful fibrous roots, may be obtained as Standards, Standards trained, Pyramids, Espaliers, Dwarfs, Dwarfs trained, Cordons, Maidens, and Bushes. APPLES can be had on Rivers' Paradise Stocks; PEARS on Quince, double-worked; CHERRIES on Mahaleb.

THE ROSE LIST CONTAINS—

- | | |
|--|---|
| NEW ROSES,
HYBRID, PERPETUAL, NOISETTE,
As Standards, Dwarfs, Half-Standards and Pot Plants. | TEA, BOURBON, CHINA; MOSS, and
SUMMER ROSES, |
|--|---|

It is well known that Kent, "The Garden of England," is noted for its Fruit—notably CHERRIES and COB NUTS; and T. B. & SONS can supply the Amateur with his dozens of Trees, or the Market Grower with thousands.

THE OLD ESTABLISHED NURSERIES, MAIDSTONE, & ROSE NURSERIES, ASHFORD.

Free by Post, 3s. 6d.,

THE ORCHARDIST.

ALL FRUIT GROWERS SHOULD OBTAIN A COPY BEFORE ORDERING THEIR TREES.

Apply to J. SCOTT, The Royal Nurseries, Merriott, Somerset,

Whose Collection is the finest in the Kingdom—2000 sorts of PEAR, 1500 sorts of APPLE, 150 sorts of PLUM, with other kinds in proportion, being grown. The great bulk of these are described in the "ORCHARDIST," the best work on Fruit Trees in the English language.

The Advertiser has numbers of Letters from Britain, America, Australia, France, Belgium, &c., all eulogising the work as the best the writers have seen.

The Trees are this season in fine health. Price Lists forwarded.

Copies to be had at

37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.

FRUIT TREES.

We would respectfully call attention to our unrivalled General Collection of the above, the Culture of which has long been a speciality with us. Our Trees this season are in a thoroughly clean and healthy condition, and true to name.

We have also a very fine Stock of GRAPE VINES for Fruiting and Planting, which we can confidently recommend.

Our new Descriptive CATALOGUE will be published shortly, and forwarded, post-free, on application.

OSBORN & SONS, Fulham Nurseries, LONDON, S.W.

ORANGE TREES.—Two for Sale, 6 feet high, 3 and 5 feet through, in good condition, full of fruit and just off bloom, in 15 and 18 inch pots. To be sold in consequence of space required. £8 8s. the pair.

J. H. PEMBERTON, Havering, near Romford.

FOR SALE, FOUR fine ORANGE TREES, fit for a large Conservatory, varying from 7 to 8 feet high from the tub to the top of tree; and one Smaller One, grown like a Bush. Enquire by letter, directed to M. H., Acworth's Post-office, Broadway, Ealing, W.

VINES.—Magnificent Canes, splendidly ripened, short jointed, all leading kinds, for Fruiting or Planting. Cannot be surpassed. Warranted clean. Inspection invited. The Trade supplied. PRICED LIST on application to FRANCIS & ARTHUR DICKSON & SONS, The "Upton" Nurseries, Chester.

Vines and Strawberries,

"Plant now to ensure a full crop of fruit next season."

FRANCIS R. KINGHORN begs to announce that his stock of VINES, including all the leading varieties, is very extensive, and in excellent condition this season. The Canes are very fine, well ripened, and perfectly free from disease. Strong Planting Canes, 3s. 6d. to 5s. each; strong Fruiting ditto, 7s. 6d. to 10s. 6d. each.

Also his collection of STRAWBERRIES includes all the most popular kinds, and are ready for immediate planting. Price, in small pots, 16s. to 20s. per 100; from the open ground, 3s. to 5s. per 100.

Less numbers than 100 of any variety can be had, if desired. Prices to the Trade and LISTS post-free, on application. Sheen Nursery, Richmond, Surrey.

Fifty Acres of Fruit Trees.

STRONG, HEALTHY, and WELL-FORMED. See RICHARD SMITH'S FRUIT LIST, which contains a Sketch of the various forms of Trees, with Directions for Cultivation, Soil, Drainage, Manure, Pruning, Lifting, Cropping, Treatment under Glass; also their Synonyms, Quality, Size, Form, Skin, Colour, Flesh, Flavour, Use, Growth, Duration, Season, Price, &c., free on application.

To Nurserymen and Others.

TO BE DISPOSED OF, one of the oldest established NURSERY BUSINESSES in the North of England, with valuable connection.

The executors of the late Mr. John Harrison, of the North of England Nurseries, Catterick Bridge and Scorton, are open to treat with a gentleman possessing capital, for the disposal of the business, which has an established connection of nearly 50 years.

The Nurseries consist of about 60 acres of Freehold Land, about 40 acres of which are stocked with a choice Collection of Roses and General Nursery Stock. There are good Residences in the Grounds, and fine Ranges of Glass, close to the Catterick Bridge Station of the North-Eastern Railway, situate between Darlington and Richmond, and offering unusual facilities for doing a large and profitable business. A large portion of the purchase money could remain on security of the property at a reasonable rate of interest. Possession could be given at any time as a going concern. Principals or their Solicitors only may apply to the undersigned,

A. E. HARRISON, Solicitor, Church Yard, Rotherham.

To Strawberry and Fruit Growers.

THE LEASE to be SOLD of 3 1/2 acres, in full bearing, of the finest sorts of Strawberries, and an Orchard of Fruit Trees. Rent, £16 per annum.

W. EATON, Chase-side, Southgate, N.

TO BE LET or SOLD, a small FREEHOLD NURSERY, within easy distance of Covent Garden, and close to Railway Station. Apply E. P., Mr. Cullens, Confectioner, High Road, Leytonstone, S.

TO BE LET, an old-established NURSERY, with which a SEED BUSINESS has been connected, in a Cathedral Town, 60 miles from London, and within easy access of the South Coast Watering Places. The extent of the Nursery is from 3 to 6 Acres, with considerable breadth of Glass, and Cottage. Energy, practical knowledge, and moderate capital would ensure a profitable business.

Address X., care of Messrs. Rutley & Silverlock, 472, Strand, London, W.C.

Cheltenham.

To FLORISTS and GARDENERS.

TO BE LET, the old established NURSERY BUSINESS, London Road, Cheltenham. The premises comprise good Dwelling-house, with gas laid on; five Green-houses, 40 to 60 feet long; long range of Pits, the whole well heated by hot-water. One Acre of Land planted with Violets, Roses, and other Plants. Stock consists of Camellias, Eucharis, Stephanotis, Azaleas, Gardenias, Ferns, early Pelargoniums, quantity of Scarlet Geranium for winter flowering, for which, with other cut flowers, there is a great demand; also stock of Bedding Plants.

For further particulars, apply to F. EARWOOD, on the Premises, Charlton Nursery, London Road, Cheltenham.

THE

IMPROVEMENT OF LANDED ESTATES, By DRAINAGE, ENCLOSING, CLEARING, THE ERECTION OF FARM BUILDINGS AND COTTAGES WATER SUPPLY, &c.

The Land Loan and Enfranchisement Co.

(Incorporated by Special Act of Parliament)

ADVANCES MONEY:

1st.—To the OWNERS of SETTLED and OTHER ESTATES, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing and General Improvement of Landed Property in any part of the United Kingdom.

2d.—To the OWNERS of SETTLED ESTATES in ENGLAND, for the Erection or Completion of Mansions, Stables, and Outbuildings, and for the Construction or Erection of Reservoirs, and other Works of a permanent nature, to supply Water for the use of the Estate, or for any other purpose.

3d.—To LANDOWNERS generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.

4th.—To INCUMBERTS, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.

5th.—To COPYHOLDERS, for the Enfranchisement of Copyhold Lands.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years.

No Investigation of the Landowner's Title is necessary.

Form of application, and all further particulars may be obtained of

Messrs. RAWLENCE AND SQUAREY, 25, Great George Street, Westminster, S.W., and Salisbury; of Messrs. ASHURST, MORRIS, CRISP, AND CO., 6, Old Jewry, London, E.C.; of Messrs. GILLESPIE AND PATERSON, W.S., 87A, George Street, Edinburgh, Agents for the Company in Scotland; and at the Offices of the Company, as below.

T. PAIN, Managing Director, EDWIN GARROD, Secretary.

Land Loan and Enfranchisement Company, 22, Great George Street, Westminster, S.W.

The Best Hardy Bedding Plant.

CLEMATIS JACKMANII.—Flowers rich purple, 4 inches across, and so profuse as to completely cover the bed. Begins to bloom in June, and continues until severe frost. It is perfectly hardy, and the stools improve annually. The only secret of success is a rich soil, to keep up free growth. Strong plants in pots, 12s. per dozen; extra strong plants, 2 years old, 18s. per dozen. Other sorts of Clematis and Climbers in great variety. Descriptive LIST on application.

RICHARD SMITH, Nurseryman, Worcester.

A B C Descriptive Bulb Guide.

THOMAS S. WARE has pleasure in announcing that the above for the present season is now ready, containing complete Lists of Lilliums, Narcissus, &c.; also a selection of Terrestrial Orchids, Bamboos and Ornamental Grasses, Climbing Plants and Herbs; to which is added an abridged List of Hardy Perennials adapted for autumn planting. Post-free on application.

Hale Farm Nurseries, Tottenham, London.

HEATHERSIDE NURSERY, between Farnborough and Bagshot, Surrey. The attention of Gentlemen and others is called to the large and varied stock of CONIFERS, Hardy, Evergreen, and Flowering SHRUBS; Trained, Pyramid and Standard FRUIT TREES; Forest and Ornamental TREES, ROSES, &c.; Hardy CLEMATIS and IVIES, &c., in Pots, at low and reduced prices. Priced CATALOGUE sent post-free.

Address, HENRY S. HEPBURN, Manager.

To the Trade.

MESSRS. LEVAVASSEUR AND SON, NURSERYMEN, Usy, Calvados, France, have an immense stock of Seedling FOREST TREES, Hardy Conifers, and other SHRUBS, for transplanting and transplanted; several millions of 1-year THORN. Priced CATALOGUES may be had of

Messrs. R. SILBERRAD AND SON, 5, Harp Lane, Great Tower Street, London, E.C.

TO GENTLEMEN INTENDING TO PLANT.—In consequence of the decease of the late Mr. R. W. Grant of Croydon, near Reading, his valuable Collection of Young Prize NUT TREES, of named sorts, are offered at half the usual selling prices. Printed LISTS will be forwarded on application.

Immediate Orders are solicited, as the Trees will be supplied in the rotation in which the orders are received; delivery commencing on October 1. Apply to

The MANAGER, Calcot Gardens, near Reading, Berks.

GOOSEBERRIES, strong, 10s. to 12s. 6d. per 100.

CATALOGUES can be had on application to The Nurseries, Milton, Stoke-on-Trent.

NEW LATE-KEEPING BLACK GRAPE,

“ALNWICK SEEDLING.”—This Grape was exhibited before the Fruit Committee, South Kensington, February 6, 1877, under the name of Clive House Seedling, a name the Committee have since thought fit to alter. The following is the description given by the Fruit Committee:—“It is a seedling between the Black Morocco and an unnamed variety raised at Wortley. The bunch shown was of fair size and well shoudered, and the berries large, oval in form, and jet black in colour, with a thick skin. The flavour was decidedly good, partaking of the rich sparkling flavour of the Black Morocco, but much sweeter. It has kept well in February, and will, no doubt, keep longer, and prove a better Grape for general cultivation than the Black Alicante.” This has been awarded a First-class Certificate.

B. S. W. has much pleasure in offering this fine new Grape, believing it to be a decided acquisition. The stock offered is from the original plant. Early orders are respectfully solicited, as the stock is limited. Price 21s. and 42s. each.

NEW FIG, “HARDY PROLIFIC.”—The fruit of this hardy Fig is about the medium size, Pear-shaped, rather tapering towards the stalk. The flesh is very sweet, and luscious. It was introduced from France some few years ago, and has proved itself perfectly hardy. It must become a general favourite, as it is a very abundant bearer, either in pots or in a cold house, as well as on an open wall. It also ripens earlier than any other variety we know of. Price 10s. 6d. each. Extra sized fruiting plants, 21s. each.

B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London, N.

6000—Camellias—6000.

H. WALTON begs to call attention to his extensive collection of the above, of all sizes, from 42s. 63s., 105s., to 120s. per dozen; large handsome plants of all the best varieties, from 21s. to 105s. each, all home grown.

AZALEAS, all the leading varieties in fine healthy plants, from 24s. to 63s. per dozen.

A large quantity of Specimen **STOVE** and **GREENHOUSE PLANTS** in fine condition.

ERICAS, in Half and Quarter Specimens, all the best Exhibition varieties.

Inspection invited. Edge-and Nurseries, Brierfield, near Burnley, Lancashire. See Report No. 199, page 212, Aug. 18, 1877.

WILLIAM HEATH AND SON, Nurserymen and Seed Merchants, Cheltenham.

ISAAC DAVIES

Has now to offer a fine Stock of the

RHODODENDRONS and AZALEAS

RAISED BY HIM,

And which have been exhibited at various Flower Shows, and have received First-class Certificates of Merit.

SWEET-SCENTED RHODODENDRONS.

R. COUNTESS OF DERBY.—This is the most beautiful Rhododendron of its class. It is bushy-growing and very free blooming, the smallest plants bearing flowers which are pure white, very large, and most deliciously scented. Prices, 7s. 6d., 10s. 6d., 21s. each; a few extra large, 42s. and 63s. each.

R. COUNTESS OF SEFTON.—White with band of rosy purple on each side of the corolla, fringed margin. Prices, 3s. 6d., 5s., and upwards to 42s. each.

R. LADY SKELMERSDALE.—Pure white, exquisitely formed trumpet-shaped flowers, even edges and of great substance. Prices, 3s. 6d., 5s., and upwards to 42s. each.

R. MRS. JAMES SHAW.—Pure white, extremely free-blooming, and very bushy habit. Prices, 3s. 6d., 5s., and upwards to 42s. each.

R. DUCHESS OF SUTHERLAND.—Pure white flowers, fringed margin. Prices, 3s. 6d., 5s., 10s. 6d., and 21s. each.

The above are admirably suited for Growing in Cold-houses, without the necessity of artificial heat.

SWEET-SCENTED AZALEAS.

AZALEA DAVIESI.—Bears fine trusses of pale sulphur flowers, which change to white. This Azalea is perfectly hardy and very suitable for forcing. Good plants with flower-buds, 2s. 6d., 3s. 6d., and 5s. each.

A. HYBRIDA ODORATA.—A hardy bushy plant, bearing trusses of pure white sweet-scented flowers. Good plants 2s. 6d., 3s. 6d., and 5s. each.

RHODODENDRON MULTIFLORUM, fine bushes, covered with flower-buds, 2s. 6d. to 3s. 6d. each.

R. PRÆCOX, fine plants, well budded, 1s. 6d. to 2s. 6d. each.

R. PRÆCOX RUBRUM, well budded, 1s. 6d. to 2s. 6d. each.

R. PRÆCOX SUPERBUM, well budded, 1s. 6d. to 2s. 6d. each.

The above being Plants that were raised by me, I can recommend them with confidence.

CATTLEYA DOWIANA.

MR. J. C. STEVENS will SELL by AUCTION, at his Great
Rooms, 38, King Street, Covent Garden, W.C., on TUESDAY, September 25,
at half-past 12 o'Clock precisely, an importation from Costa Rica of fine plants of the beautiful
CATTLEYA DOWIANA. The plants imported are in the best possible condition, nearly the
whole with good leaves, and may be relied on as all true to name. This Cattleya is now
extremely rare in its native habitat. At the same time will be sold a quantity of other very rare
ORCHIDS, in good established and semi-established plants, such as

ODONTOGLOSSUM VEXILLARIUM
CYMBIDIUM EBURNEUM
EPIDENDRUM VITELLINUM MAJUS
ZYGOPETALUM GAUTIERI
LÆLIA ANCEPS
ODONTOGLOSSUM ROEZHII

CALANTHE MASUCA
BATEMANIA WALLISII
LÆLIA ELEGANS
CATTLEYA WAGNERI
ODONTOGLOSSUM PHALÆNOPSIS
BARKERIA ELEGANS

And the new and rare PHALÆNOPSIS VIOLACEA. Also many other extremely rare
ORCHIDS.

On view the morning of Sale, and Catalogues had.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN,
LONDON, W.C.

DENDROBIUM BIGIBBUM and DENDROBIUM
BIGIBBUM SUPERBUM.

MR. J. C. STEVENS has been instructed by Mr. B. S. WILLIAMS,
Victoria and Paradise Nurseries, Upper Holloway, N., to SELL by AUCTION, at his
Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY NEXT, September 27,
at half-past 12 o'Clock precisely, a splendid lot of this fine Orchid. The plants are in excellent
condition, and are breaking freely into growth. The lot of D. bigibbum superbum is undoubtedly
the finest ever imported, and is said by the Collector to be far superior to the old variety grown
under that name. Many of the bulbs measure from 18 to 24 inches in length.

ON VIEW THE MORNING OF SALE.

THE QUEEN'S SEEDSMEN, READING.

SATURDAY, SEPTEMBER 22, 1877.

APPLES.

OF all the fruits in cultivation there is none of such importance in this country as the Apple. Another advantage it possesses is that it can be grown successfully in most parts of the country; undoubtedly it will succeed much better in some soils and situations than in others, but if suitable kinds are planted they will answer in most districts where any of the better character of fruits will grow. That there has of late years been a greatly increased demand for Apples as an article of food, especially in large towns, there is abundant and conclusive evidence to prove, and in seasons such as the last, and still more the present, when the failure of the crop is so general, there is usually an outcry in the horticultural papers about the necessity for planting more Apples, and this is no doubt correct, and a most desirable consumption, providing that the most suitable soils and situations are selected, the ground properly prepared, and, what is of special importance, the planting confined to the most generally useful and productive kinds, more particularly such as will keep well.

APPLES ON WASTE LANDS.

Many who have expressed their views on this subject, urge that waste lands and railway embankments should be utilised by planting with Apples. Now, any one acquainted with rural matters is aware that the unreclaimed lands in this country consist of commons, unfertile moors, and peaty tracts. As to the two latter descriptions of land, it would be useless to attempt Apple culture upon them, for the simple reason that the trees would grow little and fruit less. The limited area of commons suitable for apple cultivation still remaining unreclaimed would have little influence upon the supply, and there is not much likelihood of much more of such lands being enclosed at all. As to growing Apples on the railway embankments, those who advocate the attempt evince a lack of knowledge of the requirements of the Apple, or they know nothing of what the railway slopes and embankments in this country really are. I am aware that in some places in France and Belgium Apples and Pears are grown with more or less success in this way, but in this, as in other small matters, I have no doubt that in those countries they have looked further ahead in the construction of their railways than we have done. If in the making of railways the whole of the good upper soil had been removed from the top where the cuttings had to be gone through, and also from the surface where the embankments had to be made, and this good soil had been afterwards laid on the slopes, then there might have been a possibility of growing something, if not Apples, profitably upon them; but instead of this the best soil has been almost without exception buried to an extent that has not left enough to cover the slopes 6 inches in thickness. There is not one acre in fifty of these slopes that would pay for cultivation under any fruit or vegetable crop.

To grow Apples successfully good soil of considerable depth is needed, and it is much better when of rather a heavy than when of a light character. The description of the subsoil is also of importance; if this is of a nature deleterious to the health of the trees, and sufficiently open for the roots to enter it, they will not long remain in a fruitful state. Where the top soil is from 15 to 24 inches in depth, not too light, and the under surface of fair quality, it may be relied upon to grow Apples satisfactorily; they also like to be moderately sheltered. Where the situation

is naturally exposed to cold, sweeping winds, a thin belt of deciduous or coniferous trees to protect them is of material advantage. Apples will not do on wet land, and where the soil holds too much water it must be sufficiently drained. Neither will they succeed under the opposite condition of being too dry. Where the subsoil is of a sandy or gravelly character, and the upper surface wanting in depth, and too open, the trees suffer in dry summers to an extent that prevents their either growing or fruiting as they ought.

ORCHARD OR MARKET GARDEN CULTURE.

Before proceeding to plant Apples it is well to consider under what system of cultivation they are to be grown, so as to enable the right description of trees to be selected. Where the intention is to ultimately devote the whole of the ground to the Apples, laying it down in grass when the trees have attained a considerable size, as is usual with large orchards in places distant from a market, where other produce grown in the spaces betwixt the trees cannot conveniently be disposed of, then standard trees on free-growing stocks are no doubt the best; but where, as in market gardens within a moderate distance of large towns, produce of all kinds can be disposed of without involving too much time and cost in carriage, it then becomes a question whether smaller trees, grafted on a stock that will favour less growth with a greater disposition to fruit in a smaller state, are not better, for although trees of this character have not hitherto been used to any great extent by growers of this description, still there are some who have tried them with satisfactory results. The advantage is that the bush fruits and collards usually grown in intermediate rows between the Apples do much better consequent upon being less shaded by the smaller trees and by planting the Apples closer, which the less size of the trees admits of, the crop obtained is equal in quantity to the produce of the standards. Moreover, from the slight pruning the smaller trees are subject to, and the higher cultivation consequent upon digging and manuring for the bush fruits, &c., the Apples are finer. The advantage derivable from the ground being thus occupied by Apples, Pears, Plums or Cherries, with rows of bush fruits intervening, is that whilst they do not interfere with the health of these smaller fruits, they afford considerable protection to their bloom from spring frosts. Under the conditions of partial shelter it often happens that a crop is secured from the bush fruits, whereon, if grown by themselves, the bloom would have been destroyed, which is so much gained even if the Apple bloom is killed. In private gardens, even of considerable size, there can be little doubt that these medium-sized trees are the best, as large standards are so injurious in their effects upon culinary vegetables and other things that often perforce must be grown near them. In small gardens, where standards have acquired anything approaching their full size, their adverse influence in this respect is even worse, and they always look out of character, in addition to which the space they occupy does not admit of sufficient variety, and in seasons when they fail to crop their presence is doubly objectionable.

CORDONS.

The small miniature bush-shaped trees and cordons that find favour with some persons are interesting enough in their way, and serve the purpose of those who are more anxious to grow a large number of varieties on a small space than to have a plentiful supply of good useful kinds. These little toy trees, that a few years ago were so persistently belauded, are poorly calculated to fill the Apple store.

PLANTING APPLES.

In breaking up new ground for planting Apples it should be trenched from 15 to 18 inches deep, according to the depth of the soil, but I should not advise the bottom spit being brought up to the top, merely turning it over and keeping it underneath. If the land is good in quality it will be better not to dig in or use any manure at the time of planting, as the trees will make quite growth enough for a few years without it, and stimulants of this kind can be given whenever required; and when thus applied later on it will necessarily be dug in only a little below the surface, which will have a beneficial effect in inducing the roots to keep near the top—a condition of the greatest importance. In old gardens the addition of a portion of fresh soil, or trenching deep enough to

bring up some new to incorporate with the old, will in most cases be of more use than heavy dressings of manure. In situations where the land is naturally moist, or the rainfall considerably above the average, in addition to sufficient drainage I have found it much better to plant upon the surface than to make holes in the usual way, covering the roots to the required depth with soil from betwixt the rows. There is a double advantage in this: the roots, from being so placed, are afterwards more under control, and the drier bed they thus occupy is more favourable through the advanced summer and autumn to the formation of fruit-buds than the production of wood. This method of planting, from the greater depth it gives to the roots, is an advantage where the soil is shallow. There are two other matters that I would urge the importance of: never plant deep, and never defer planting later in the autumn than can be avoided. If I were planting Apples by the acre, I should try to get them all in during the latter end of October. As to pruning, all that is required is to shorten back any over-strong shoots that are taking an undue lead, and to thin out the weaker ones, so as to give enough room to all that are retained. The summer pruning advocated by some people, by repeatedly pinching the shoots, is about as great a mistake with anything but the diminutive toy trees as ever was introduced into anything connected with horticulture. When the trees have got established a few years, any inclination to over-luxuriate, with consequent indisposition to bear, and later still, should they appear to be getting too large for the position they occupy, root-pruning should be resorted to, always performing it early enough—the end of August and beginning of September I have invariably found to give the best results. Root-pruning in the spring is highly injurious.

SELECTION OF KINDS.

In the cultivation of this fruit there are two mistakes very often made—the selection of varieties unsuited to the soil and climate, and planting too many kinds. Amateurs and those who have not much experience in any particular locality, will always do well before planting to look round and see what sorts succeed best in the neighbourhood, and keep to such; and even where all the conditions are favourable to Apples of most kinds, it is much better to limit the planting to a few of the best sorts that come in for use at the different seasons, and that are the most certain and free bearers. However fine in quality any particular variety may be, if it is a shy bearer it is worse than useless; for instance, Cornish Gillyflower may be the finest flavoured Apple in existence, and unsurpassed in texture, but in nine places out of ten throughout the kingdom where Apples are grown it will not produce as many Apples as there are trees, one year with another.

List of the best varieties:—

Kitchen Sorts.

Lord Suffield
Kewick Codlin
New Hawthornden
Cellini
Eckinville Seedling
Blenheim Pippin
Nelson Codlin
Yorkshire Greening
Bedfordshire Foundling
Dumelow's Seedling
Alfriston
Froech Crab

Dessert Sorts.

Irish Peach
Devonshire Quarrenden
Kerry Pippin
Ribston Pippin
Margil
Cox's Orange Pippin
Boston Russet
King of the Pippins
Court Pendu-Plat
Sykehouse Russet
Cockle Pippin
Sturmer Pippin

These twelve dessert and twelve cooking varieties of Apples may appear a very short list to those who have a leaning for variety rather than quality and quantity, with a continuous supply over the greatest part of the year, but the above sorts combine general excellence in flavour and texture of the fruit with a free bearing disposition; they are good growers in most parts of England, and unless where the space that can be devoted to the culture of this fruit is in no way restricted, I would much rather plant several trees of each of the above kinds than extend the number of the varieties. *Zel.*

New Garden Plants.

ONCIDIUM CHRYSOMORPHUM, Lindl. *Fol. Orchid.*;
Oncidium, No. 188.

A VERY unexpected surprise it was to see lately this obscure plant as a hodgepodge of English flowers. The flower panicle is described as 12 inches long, thickly branched, and very pretty in the mass. Dr. Lindley has very well compared it with *O. anomalum*, Rehb. f. (*panchrysium*, Lindl.). It is stouter, thicker, has broader leaves, much broader pseudobulbs, and a stronger inflorescence. The branchlet at hand has no heteranthous flowers. It is to be regretted that neither Sir William nor Sir Joseph Hooker has ever pub-

lished the representation prepared by Mr. Fitch, and quoted by Dr. Lindley ("Lindl., in *Bot. Mag.*, ined."). Is it to keep Dr. Lindley's word "ined." perpetually accurate, or is it the consequence of certain letters addressed by subscribers complaining of *Oncidi* having yellow flowers? Is so, why not complain, also, of their having usually green leaves? As it is, the plant is of botanic interest, and I feel very grateful to Mr. Sergeant Cox, Moat Mount, Mill Hill, N.W., for the sight of it. *H. G. Rehb. f.*

EPIDENDRUM COXIANUM, n. sp.*

A botanic curiosity, having fusiform pseudobulbs with ligulate leaves. It flowers in a panicle, as I am informed, from the young shoot. The rachis is viscidose. The bracts are unusually developed, and remind one, as does the whole shape of flower, of *Epidendrum clavatum*, Lindl. The numerous flowers have "brownish yellow sepals, the throat is pale green, the labellum pale yellow." Origin: Mr. Stevens' inexhaustible store-rooms. I have to thank for materials and information about the stem, leaves, and colour, Mr. Sergeant Cox, of Mill Hill, near London, a most ardent grower of Orchids, with whom it has flowered, and to whom the novelty is dedicated. *H. G. Rehb. f.*

GREENHOUSE PLANTS.

THEIR CULTURE AND MANAGEMENT.

THE CAMELLIA (*concluded from p. 298*).—After potting, replace them in the house or pit they have previously occupied, keeping them a little close and shading as heretofore, syringing in the afternoons. They will not need water at the root for some days, during which time any roots that have been broken will have time to heal. The reason for potting Camellias at a time when their growth is approaching completion, and different from that found the best for most plants, is that early in the season, for some time previous to any development of top growth, their roots are actually at work, and from their exceptionally brittle nature, especially whilst young, they cannot be disturbed without injury to an extent that generally seriously interferes with the top growth for the season. The evil consequences of this are avoided by moving them at the time here advised; but the potting, particularly with plants that have acquired considerable size, and whose flowering is of much consequence, must not be deferred too long, that is until the flower-buds have grown to any considerable size, or the inevitable result will be that they will fall off. The roots will soon enter the new soil, as, when the plants are in good health, they keep on growing after the wood-growth is completed. They will now require no warmth, simply ordinary greenhouse protection, with plenty of air, but should be slightly shaded during the middle of the day, when the weather is bright, so long as the sun is powerful. The soil even during the autumn and winter must never be allowed to get dry. As to temperature, they will need nothing more than sufficient to keep out frost.

From their natural free disposition to flower, even in a very small state, they will bloom the ensuing spring, but if their flowers are needed for cutting, they should not have much or any of the wood cut with them whilst so young, or it will seriously interfere with their growth; but for most purposes in which Camellia flowers are now used, they are cut or twisted off without any wood attached, and afterwards mounted on wires, which is a great gain to the plants, even when large and strong, as it enables them to produce a full crop of flowers every year, which was not the case when many of the shoots were cut with the flowers, a practice frequently carried so far as to bring about a stunted, unhealthy condition. Each subsequent year's treatment will need to be similar to that advised for the first, so far as warmth, shade, and moisture during the season they are making their growth, potting at such intervals as they require it; but this will not be necessary every year, even in their younger stages, and as they get large they will frequently go on for years without additional room. At the same time, they must not be too much confined at the root, and whenever they evince signs of weakness by making less growth they should be moved to larger pots or tubs. As they get big enough for the

* *Epidendrum Coxianum*.—(Osmophyllum) labello apiculato; pseudobulbo fusiformi, uni usque "diphylo"; foliis ligulatis coriaceis; panícula diffusa; rachis compressa viscida; bracteis scariosis triangulis ovarii pedicellati tertiam partem æquantibus; sepalis lanceis cuspidatis; tepalis angustioribus; labello omnino adnato circulari apice cum apiculo; carinis ternis in basi, externis basi obtusangulo elevatis; androclinio lobulato. "Sepala et tepala brunneo-flava; labello pallide flavum."—Ex coll. E. W. Cox.

latter, any branches that show a disposition to out-grow and impoverish the weaker ones should be shortened back and bent down, but with sufficient room and fair treatment. When the training has been properly attended to in the early stages of their existence, the natural habit of most varieties is such as to entail little difficulty on this head.

Some growers fully expose their plants out in the open air during the summer after the flowers are set; but this is a bad practice, as if stood where the foliage is sufficiently shaded by trees or walls to prevent its getting discoloured by the sun, they are exposed to heavy rains, whereby the soil gets saturated to an extent that causes it to become sour, often inducing a diseased condition of the roots, or, if less serious in its consequences, causing the buds to fall off later when they should be near approaching expansion. A similar result in the buds dropping will follow if the plants ever get too dry at the roots after the buds have attained any considerable size, or if they are kept in too high a temperature with insufficient moisture in the atmosphere; in fact, Camellias will not bear any attempt at forcing, although some kinds open their flowers much more freely in a temperature a little above that of an ordinary greenhouse, but where there is a disposition to accelerate their flowering, 45° to 48° in the night, with 6° or 8° more in the day, is hot enough.

When Camellias are required to bloom earlier than they have done the preceding year, the time to regulate this is after the flowers are set, by keeping them in heat until the buds are grown to a size that will enable them to expand without the application of anything much above a greenhouse temperature, after they have once been removed from the warmth to which they have been subjected whilst making growth and setting their buds, for, though they may be kept in a temperature such as existed whilst the growth was being made, even until the flowers expand if such were desirable, yet when once they have been removed from the influence of such heat it appears to induce a slower condition of flower development that will bear little attempt at acceleration. Camellias look well trained over a back wall in a greenhouse or cool conservatory, where such exist as are suitable for the purpose, either grown in pots, tubs, or planted out. In the latter way they increase in size much the quickest, as in like manner they do when planted out in a well prepared bed in the body of the house. So treated; they thrive in a way that cannot be equalled by pot or tub culture; but when they are to be grown in this manner they should not be planted out in a very small state, as when thus turned out the limited quantity of roots they possess are not able to take hold of the large body of soil before it gets into a soddened state. The principal objection to planting a collection of Camellias out is, that the system does not admit of a portion of the stock being removed to cooler quarters after the buds are set, so as to retard their flowering, and thus afford a longer succession, or of starting some later with the same object; neither can the plants be so readily washed with any insecticide for the destruction of insects.

When Camellias that have attained a moderate or considerable size happen to get into a stunted condition, with an insufficiency of branches and foliage, there is no method equal to planting out for restoring them to health; where this has to be done, a bed of good turfy loam or peat, if the plants are much enfeebled, should be prepared, with enough sand added to ensure porosity. It should be made at least 6 inches deeper than the depth of the balls of the plants, and the bottom well and carefully drained; into this they should be turned out, either in spring before growth commences, or, better, after the growth is fully completed; but in the case of plants in the state under consideration the later time of moving is not of so much importance. To prevent any possibility of the balls getting dry it will be well to puncture them freely from the surface to the bottom with a stout iron wire in the form of a skewer. With the same view, also, the soil surrounding the ball must be well-rammed, and made an inch or so higher than the surface of the ball, so as to force the water given through it. After the first season, when the roots have extended, the soil thus raised may be levelled down. Camellias so treated generally break out quantities of young shoots from the old wood, and in a few years get dense and full of growth, when, if desired, they may be taken up and replaced in pots or boxes. This should be done as soon as the buds are set, keeping the plants close for some weeks. If the

operation is carefully carried out, and they are afterwards fairly treated, they will generally flower freely the ensuing winter and spring.

When Camellias get into a straggling, naked condition it is frequently desirable to cut them right back to the strong branches, or to head down so far, removing the top altogether to within 8 or 9 inches above where grafted. The union with the stock is usually easily to be seen, and although no eyes on the stem are perceptible, it will break into growth at every place where there was a leaf during the earliest existence of the scion; but heading down, or even cutting back to any extent, should never be attempted unless the plants are fairly stocked with healthy roots, or death will most likely be the result. The operation ought to be carried out in the spring, a month or so before the wood-buds have begun to swell; if deferred later, the stools generally bleed to an extent that does them much injury. When headed down they should be placed in a gentle heat and the soil kept slightly moist, but not wet. When broken fairly a little more water may be given. Keep during the summer in a growing temperature, with a moderately humid atmosphere. They usually make long, vigorous growth, which will need stopping and slightly tying out so as to make them shapely.

The after treatment required will be of a similar nature to the ordinary stock. There is some difference of opinion amongst growers of Camellias as to the use of manure-water. I have tried liquid stimulants of different kinds, and have found them decidedly beneficial, especially to plants that are rather deficient in pot-room when given just before and during the season of their making growth, but at no other time. Liquid from stable manure with a little soot added will well answer the purpose.

Camellias suffer from most insects that infest pot-plants, although it is only in extreme cases of neglect that thrips or red-spider do them harm; mealy-bug will live and thrive upon them, but from the nature of both wood and leaves is easily removed; brown-scale is also sometimes troublesome, increasing fast during the growing season, but as it confines itself principally to the leaves, it is easily removed by sponging; white-scale is their greatest enemy, and is difficult to eradicate if once it gets to a head, getting into every crevice in the bark, on the shoots, the leaves, and on the buds. Careful and thorough brushing, with the use of a small pointed stick of soft deal to get into the crevices where the insect takes up its quarters, sponging the plants afterwards, is the best method of keeping down the pest.

The following is a list of the best kinds, old and new:—

Alba plena (old double white): still unsurpassed for all purposes.

Valtevareda: bright rose, sometimes spotted with white; imbricated. A large and magnificent flower.

Contessa Lavinia Maggi: white, striped with carmine; flowers very large. Unsurpassed amongst the striped varieties.

Targioni: white striped with cerise; a beautiful imbricated flower.

Teutonia: pale rose striped with white.

Jubilee: a pinkish white, specked and splashed with rose.

Mathotiana: large, rich crimson; imbricated. A magnificent kind.

Mathotiana alba: pure white, similar in every respect to the preceding, except colour. Very fine.

Chandler: a strong growing crimson, very showy.

Vicomte de Nieuport: beautiful rose, large, and finely imbricated.

Bealii: very deep crimson. One of the best kinds; flowers late in the spring.

Candidissima: medium sized flower of the purest white; blooms late in spring. Should have a place in the most select collection.

Monarch: rich scarlet veined with crimson, irregular centre; a large fine flower.

Henri Favre: flowers beautifully imbricated; colour pinkish rose. A splendid variety.

Imbricata: the finest of all the double reds; flowers sometimes marbled with white.

Imbricata alba: white, sometimes striped with carmine; a fine variety.

Jenny Lind: white, striped and spotted with rose.

Donckelaari: semi-double, rich crimson, beautifully marbled with white.

Fimbriata: pure white, very double, splendidly imbricated, fringed petals; a superb variety.

Princess Bacciochi: deep glossy carmine, regularly imbricated; a beautiful kind.

Napoleon III.: rosy-crimson, edged with white.

Lady Hume's Blush: carmine, with a white tint—a beautiful kind, the plant somewhat straggling in growth.

Story: outer petals bright rose, with a whitish centre.

Archiduchesse Marie: red, banded with white, imbricated; flowers very double. T. Baines.

VEGETABLE PRODUCTS OF PERSIA.

SOME very interesting details on the vegetable products of Persia are contained in a recently issued report on the trade and commerce of Ghilan, Mazenderan, and Asterabad. It seems that from experiments made in the cultivation of Tobacco the result has been successful; a kind known as "Samsoun" is grown in small quantities in the neighbourhood of Resht, from seed brought from the shores of the Black Sea, and although it has been grown and prepared by inexperienced hands it yields a Tobacco of good quality and aroma. This success has encouraged the natives to turn their attention to Tobacco growing, preparations having been made to cultivate it on a large scale during the present year; a company has also been formed with the same object, and special Tobacco growers have been induced to take up their quarters in Resht for the purpose of carefully cultivating the plant. It was estimated at the time the report was written that this year's produce would amount to 1000 cwt.

Olive Oil.—A considerable quantity of oil is yielded by the Olive groves of Rudbar, but the quality, as a general rule, is very inferior, so that it is suitable only for the manufacture of common kinds of soap; it is considered that if properly treated its value would be considerably increased. Salad oil is produced in small quantities by the Armenians, and this oil is said to be equal, both in flavour and colour, to the best Italian oil. There is ample room and good water-power accommodation in Rudbar for the establishment of several water-mills, which would open up a great branch of industry. Olives realise, on the spot, about 3s. 6d. per cwt.

Rice.—Some years ago this commodity was so little cultivated in Ghilan that it had to be imported from Mazenderan and other parts of Persia; it has now become a produce of considerable importance. Since the repeated failures of the silk crops the peasantry of Ghilan have applied themselves to clearing away the jungle and sowing Rice. This new feature in the agricultural prospects of the country, together with the cutting down of the forests, has contributed to alter the nature of the climate of these regions.

Boxwood.—During the year 1876, 2170 tons of this wood were cut down in the province of Ghilan, numbering in all 60,000 pieces. "When it is considered that scarcely more than one piece can be got out of one tree, and that hence upwards of 200,000 trees were hewn down last year alone in Ghilan and Mazenderan, it will readily be understood that, however thick the jungle may be, this extensive cutting down of the forests must have an effect on the climate of these regions, and it is to be observed that within the last few years—in fact, since boxwood has been cut, and Rice cultivated, a much smaller amount of rain has fallen on the side of the Elburz mountains, which tends to make the country less feverish and unhealthy than it was in days gone by." From the district of Tenekaboun 5800 tons of boxwood were exported during last year, one firm of proprietors having cut down nearly 170,000 trees to effect this object. Every piece of boxwood worth exporting must be at least 9 inches in diameter and between 4 and 5 feet in length. It must be straight and free from cracks, the average weight of each piece being 70 lb.; 1000 pieces of such wood is worth on the coast from £120 to £160. Tenekaboun boxwood is superior to that of Ghilan. The wood felled in these boxwood forests last year was sent to Rostow for transmission to England, but it seems the market got overstocked; and this together with the war rumours then prevalent would, it was estimated, prevent the cutting of any more boxwood during the present year. Therefore, all things considered, the high price of this wood is likely to be maintained, if not increased.

Loupes.—Under this name the large knobs or burrs of the Walnut trees are collected in great quantities. The *loupe* is described as an "article of trade much sought after in the mountains separating the Caspian provinces from Irak or Persia proper. It is only produced in the highlands, where it may be purchased

at a very low rate, but owing to the labour attending its transport in a country destitute of means of communication, it comes to cost too much for speculative purposes to bring it down to the ports of shipment. Some good specimens of this valuable excrescence were notwithstanding brought down last season to Enzelee. The best marked samples of this wood are sent to England, *via* Tiflis, while the ordinary qualities suit best the French market. Some *loupes* are to be found weighing upwards of a ton, but, owing to the want of means of transport, they have to be reduced in size. "It would repay curiosity to witness the process by which these hard blocks of timber are cut up into sheets almost as thin as writing-paper for veneering purposes. The *loupe* is introduced into a large receptacle and steamed for several days consecutively, until from the adamant hardness it naturally possesses it assumes the consistency of cheese; it is then placed under a machine, which, with a large blade, slices it off into sheets, which harden by exposure, and are sold in the market according to size and beauty of design. Some *loupes* in Paris have fetched as much as £300."

From these notes it will be seen that the forest produce of the districts under consideration are of a very valuable description. ♀

THE ROTHAMSTED AGRICULTURAL EXPERIMENTAL STATION.*

MR. LAWES was the founder of the Rothamsted Experimental Station, and commenced experiments with different manuring substances, first with plants in pots, and afterwards in the field, soon after entering into possession of his hereditary property at Rothamsted† in 1834. The researches of De Saussure on vegetation were the chief subjects of his study to this end. Of all the experiments so made, those in which the neutral phosphate of lime, in bones, bone-ash, and apatite, was rendered soluble by means of sulphuric acid, and the mixture applied for root-crops, gave the most striking results. The results obtained on a small scale in 1837, 1838, and 1839, were such as to lead to more extensive trials in the field in 1840 and 1841, and subsequently.

In 1843 more systematic field experiments were commenced, and a barn, which had previously been partially applied to laboratory purposes, became almost exclusively devoted to agricultural investigations. The foundation of the Rothamsted Experimental Station may be said to date from that time (1843).

The Rothamsted station has up to the present time been entirely disconnected from any external organisation, and has been maintained entirely by Mr. Lawes. He has further set apart a sum of £100,000, and certain areas of land, for the continuance of the investigations after his death.

In 1854-5 a new laboratory was built, by public subscription of agriculturists, and presented to Mr. Lawes, in July, 1855, from which date the old barn-laboratory was abandoned, and the new one has been occupied.

From June, 1843, up to the present time, Dr. J. H. Gilbert has been associated with Mr. Lawes, and has had the direction of the laboratory.

The number of assistants and other helps has increased from time to time. At first only one laboratory man was employed, but very soon a chemical assistant was necessary, and next a computer and record-keeper. During the last twenty-five years the staff has consisted of one or two, and sometimes three, chemists, and two or three general assistants. One of these is usually employed in routine chemical work, but sometimes in more general work. The chief occupation of the general assistants is to superintend the field experiments—that is, the making of the manures, the measurement of the plots, the application of the manures, and the harvesting of the crops, also the taking of samples, the preparation of them for preservation or analysis, and the determinations of dry matter, ash, &c. These assistants also superintend any experiments made with animals. There are now about 25,000 bottles of samples of experiment-

ally-grown vegetable produce, of animal products, of ashes, or of soils, stored in the laboratory.

A botanical assistant is also occasionally employed, with from three to six boys under him, and with him is generally associated one of the permanent general assistants, who at other times undertakes the botanical work.

Two or three (for some time past three) computers and record-keepers have been occupied in calculating and tabulating field, feeding, and laboratory results, copying, &c.

One, and sometimes two, laboratory men are employed.

Besides the permanent laboratory staff, chemical assistance is frequently engaged in London or elsewhere, and in this way, for some years past, Mr. R. Richter, of Berlin, has been almost constantly occupied with analytical work sent from Rothamsted.

The field experiments, and occasionally feeding experiments, also employ a considerable but a very variable number of agricultural labourers.

On different descriptions of Wheat, nine years, 7 acres (each year in a different field), about 20 plots.

On Beans, thirty-one years (including one year Wheat and five years fallow), 1½ acres, 10 plots.

On Beans, alternated with Wheat, twenty-eight years, 1 acre, 10 plots.

On Clover, with fallow or a corn crop intervening, twenty-eight years, 3 acres, 18 plots.

On Turnips, twenty-five years, about 8 acres, 40 plots.

On Sugar Beet, five years, about 8 acres, 40 plots.

On Mangel Wurzel, 1 year (in progress), about 8 acres, 40 plots.

On Potatoes, one year (in progress), 2 acres, 10 plots.

On rotation, thirty years, about 2½ acres, twelve plots.

On permanent grass land, twenty-two years, about 7 acres, twenty plots.

Comparative experiments with different manures have also been made on other descriptions of soil in other localities.

FIG. 71.—A, RAIN-GAUGE; B, SMALLER DRAIN-GAUGES; C, LARGER DRAIN-GAUGE.

Nothing has been done at Rothamsted in the way of manure-feeding stuff or seed control.

The investigations may be classed under two heads:—

I.—FIELD EXPERIMENTS, EXPERIMENTS ON VEGETATION, &c.

The general scope and plan of the field experiments has been:—

To grow some of the most important crops of rotation, each separately, year after year, for many years in succession on the same land, without manure, with farmyard manure, and with a great variety of chemical manures; the same description of manure being, as a rule, applied year after year on the same plot. Experiments on an actual course of rotation with different manures have also been made. In this way field experiments have been conducted as follows:—

On Wheat, thirty-four years in succession, 13 acres, 35 plots, many of which are duplicates of others.

On Barley, twenty-six years in succession, 4½ acres, 23 (or 29) plots.

On Oats, nine years in succession, ¼ acre, 6 plots.

On Wheat, alternated with fallow, twenty-six years, 1 acre, 2 plots.

Samples of all the experimental crops are taken, and brought to the laboratory. Weighed portions of each are partially dried, and preserved for future reference or analysis. Duplicate weighed portions of each are dried at 100° C., the dry matter determined, and then burnt to ash on platinum sheets in cast-iron muffles. The quantities of ash are determined and recorded, and the ashes themselves are preserved for reference or analysis.

In a large proportion of the samples the nitrogen is determined.

In selected cases, illustrating the influence of season, manures, exhaustion, &c., complete ash analyses have been made, numbering in all about 500.

Also in selected cases, illustrating the influence of season and manuring, quantities of the experimentally-grown Wheat grain have been sent to the mill, and the proportion and composition of the different mill products determined.

In the case of Sugar Beet the sugar, by polariscope, has in most cases been determined.

In the case of the experiments on the mixed herbage of permanent grass land, besides the samples taken for the determination of chemical composition (dry matter, ash, nitrogen, woody fibre, fatty matter,

* Drawn up March—April, 1877, in answer to Circular in connection with the commemoration of the twenty-fifth anniversary of the establishment of the first experimental station in Germany (Mockern), to be held in Leipzig in September, 1877.

† Rothamsted is in Hertfordshire, twenty-five miles from London, on the Midland Railway; station, Harpenden.

and composition of ash), carefully averaged samples have frequently been taken for the determination of the botanical composition. In this way on three occasions, at intervals of five years—viz., in 1862, 1867, and 1872—a sample of the produce of each plot was taken, and submitted to careful botanical separation, and the percentage by weight of each species in the mixed herbage determined. Partial separations have also been made in other years.

ANALYSIS OF SOILS.

Samples of the soils of most of the experimental plots have been taken from time to time, generally to the depth of 9, 18, and 27 inches, but sometimes to

RAINFALL.

Almost from the commencement of the experiments the rainfall has been measured—for twenty-four years in a gauge of one-thousandth of an acre area, as well as in an ordinary small funnel-gauge of 5 inches diameter. From time to time the nitrogen, as ammonia and as nitric acid, has been determined in the rain waters.

Three "drain gauges," also of one-thousandth of an acre each, for the determination of the quantity and composition of the water percolating respectively through 20 inches, 40 inches, and 60 inches depth of soil (with its subsoil in natural state of consolidation) have also been constructed. A more numerous series of smaller "drain gauges," arranged for the investiga-

plants, including representatives of the gramineous, the leguminous, and other families, have been experimented upon. Similar experiments have also been made with various trees.

BOTANICAL CHARACTERISTICS.

Having regard to the difference in the character and amount of the constituents assimilated by plants of different botanical relationships, under equal external conditions, or by the same description of plants, under varying conditions, observations have been made on the character and range of the roots of different plants, and on their relative development of stem, leaf, &c. In the case of various crops, but

FIG. 72.—DIFFERENTIAL DRAIN-GAUGES AT ROTHAMSTED.

twice this depth. In this way nearly 600 samples have been taken, submitted to partial mechanical separation, and portions of the mould have been carefully prepared and preserved for analysis. In a large proportion of the samples the loss on drying at different temperatures and at ignition has been determined. In most the nitrogen determinable by burning with soda-lime has been estimated. In some the carbon, and in some the nitrogen as nitric acid, have been determined. Some experiments have also been made on the comparative absorptive capacity (for water and ammonia) of different soils and subsoils. The systematic investigation of the amount and condition of the nitrogen, and of some of the more important mineral constituents of the soils of the different plots and from different depths, is now in progress or contemplated.

tion of the influence of different crops and of different manures, are in course of construction. Each of the differently manured plots of the permanent experimental Wheat field having a separate pipe-drain; the drainage-waters have frequently been collected and analysed. Professor Frankland has determined the nitrogen, as ammonia, as nitric acid, and as organic nitrogen, and also some other constituents, in many samples both of the rain and of the various drainage waters collected at Rothamsted; and Dr. Voelcker has determined the combined nitrogen, and also the incombustible constituents, in many of the drainage waters.

AMOUNT OF WATER TRANSPIRED.

For several years in succession, experiments were made to determine the amount of water given off by plants during their growth. In this way various

more especially with Wheat, samples have been taken at different stages of growth, and the composition determined in more or less detail, sometimes of the entire plant, and sometimes of the separated parts. In a few cases the amounts of dry matter, ash, nitrogen, &c., in the above-ground growth of a given area, at different stages of development, have been determined. The amounts of stubble of different crops have also occasionally been estimated.

ASSIMILATION OF NITROGEN.

Experiments were made for several years in succession to determine whether plants assimilate free or uncombined nitrogen, and also various collateral points. Plants of the gramineous, the leguminous, and of other families were operated upon. The late Dr. Pugh took a prominent part in this inquiry.

II.—EXPERIMENTS ON ANIMALS, &c.

Experiments with the animals of the farm were commenced early in 1847, and have been continued, at intervals, up to the present time.

The following points have been investigated :—

1. The amount of food and of its several constituents consumed in relation to a given live weight of animal within a given time.
2. The amount of food and of its several constituents consumed to produce a given amount of increase in live weight.
3. The proportion and relative development of the different organs or parts of different animals.
4. The proximate and ultimate composition of the animals in different conditions as to age and fatness, and the probable composition of their increase in live weight during the fattening process.
5. The composition of the solid and liquid excreta (the manure) in relation to that of the food consumed.
6. The loss or expenditure of constituents by respiration and the cutaneous exhalations—that is, in the mere sustenance of the living meat-and-manure-making machine.

The general plan of experimenting was as follows :—

To provide data as to the amount of food or its several constituents consumed in relation to a given live weight of animal within a given time, and to produce a given amount of increase in live weight, several hundred animals—oxen, sheep, and pigs—have been experimented upon. Selected lots of the animals were supplied for many weeks, or for months consecutively, with weighed quantities of foods, selected and allotted according to the special point under enquiry. The composition of the foods was determined by analysis. The weights of the animals were taken at the commencement, at intervals during the progress, and at the conclusion of the experiment.

The amount and relative development of the different organs and parts were determined in two calves, two heifers, fourteen bullocks, one lamb, 249 sheep, and fifty-nine pigs.

The percentages of water, mineral matter, fat and nitrogenous substance, was determined in certain separated parts, and in the entire bodies of ten animals—namely, one calf, two oxen, one lamb, four sheep and two pigs. Complete analyses of the ashes respectively, of the entire carcasses, of the mixed internal and other offal parts, and of the entire bodies of each of these ten animals, have also been made.

From the data provided, as just described, as to the chemical composition of the different descriptions of animal in different conditions as to age and fatness, the composition of the increase whilst fattening, and the relation of the constituents stored up in increase to those consumed in food, have been estimated.

To ascertain the composition of the manure in relation to that of the food consumed, oxen, sheep and pigs have been experimented upon.

In the case of oxen, the food and litter, sometimes with an acid absorbent, were weighed, sampled and analysed, the animals were fed in boxes for periods of from five to nine weeks, and the total dung produced was well mixed, weighed, sampled and analysed. The constituents determined in the food and litter on the one hand and in the dung in the other, were dry matter, ash and nitrogen.

In the case of sheep no litter was used; the animals were kept, in lots of five, on rafters, through which (but with some little loss) the solid and liquid excreta passed on to a sheet-zinc flooring at such an incline that the liquid drained off at once into carboys containing acid, and the solid matter was removed two or three times daily, and also mixed with acid. The constituents determined in the food and manure were dry matter, mineral matter, sometimes woody fibre, and nitrogen.

In the case of pigs individual male animals were experimented upon, each for periods of three, five, or ten days only. Each animal was kept in a frame preventing it from turning round, and having a zinc bottom, with an outlet for the liquid to run into a bottle, and it was watched night and day, and the voidings carefully collected as soon as passed, which could easily be done, as the animal never passed either fæces or urine without getting up, and in getting up he rang a bell, and so attracted the notice of the attendant. The constituents determined were, in the food and fæces, dry matter, ash and nitrogen, and in the urine, dry matter, ash, nitrogen, and urea.

The loss or expenditure of constituents by respira-

tion and the cutaneous exhalations has not been determined directly, that is by means of a respiration-apparatus, but only by difference, that is, by calculation founded on the amounts of dry matter, ash, and nitrogen in the food and in the fæces and urine.

Independently of the points of inquiry above enumerated the results obtained have supplied data for the consideration of the following questions :—

1. The characteristic demands of the animal body (for nitrogenous or non-nitrogenous constituents of food) in the exercise of muscular power.
2. The sources in the food of the fat produced in the animal body.
3. The comparative characters of animal and vegetable food in human dietaries.

SUPPLEMENTARY INVESTIGATIONS.

In conjunction with Professor Way, an extensive investigation was undertaken on the application of town sewage to different crops, but especially to grass. The amount and the composition of both the sewage and the produce grown were determined, and in selected cases the composition of the land drainage-water was also determined. Comparative experiments were also made on the feeding qualities of the differently grown produce, the amount of increase yielded by oxen, and the amount and composition of the milk yielded by cows being determined. In this inquiry part of the analytical work was performed at Rothamsted, but most of it by Professor Way in London.

The chemistry of the malting process, the loss of food constituents during its progress, and the comparative feeding value of barley and malt, have been investigated.

Although many of the results of the investigations above enumerated have already been published, a large proportion as yet remains unpublished.

CONCERNING GOOSEBERRIES AND CURRANTS.

THERE are Peas which are called double-blossomed, somewhat inaccurately, because their blossoms are not double. Each flower-stalk that starts from the Pea-haulm bears two blossoms, and that is all. Can a more correct name be found for them?—twin-flowering?—or what? "Double-bearing" would seem to indicate that they bore two crops a-year, which is equally untrue.

A like difficulty occurs with Gooseberries, which occasionally give two fruits hanging from the same branched footstalk. M. Carrière overcomes it by designating the varieties which manifest this tendency as "biferous," although the term is not sufficiently precise, and gives only an imperfect idea of the fact so pointed out. The essential point is, that it should denote the varieties whose fructification differs from that peculiar to the typical form of Gooseberry, *Ribes grossularia*, whose fruits are solitary, whereas these have a tendency to imitate Currants in their formation of bunches, by producing two, or even three, associated fruits, through a biferous or a multiferous effort. M. Carrière asks if the fact is exceptional—if it is capable of continued reproduction? He does not know; the future will tell; it is at least important to point it out. The occurrence, at any rate, is not unique; for in the sowing which produced the plant that attracted M. Carrière's attention, there were several other seedlings possessing the same character. Is it the beginning of the development of a new type? The thing is possible, but cannot of course be certified. This biferous seedling is moderately vigorous and much less thorny than Gooseberries in general; which, however, is not surprising, since it comes from the variety Billiard, which is almost thornless. The fruits have no particularly distinctive quality. They are of average size, slightly coloured, and of agreeable flavour, resembling that of other good varieties. Even if the biferous Gooseberry present no great interest in a horticultural point of view, the case is different when regarded botanically. By modifying the type to which it belongs, its inflorescence assimilates it to another type, a kindred species, the bunch-bearing Currant. Perhaps one of these days horticulture may succeed in making bunches of Gooseberries as familiar as bunches of Currants.

M. Carrière also recommends in the *Revue Horticole* the propagation of Gooseberries and Currants by budding, although they are usually multiplied by cuttings. The operation is performed in the same

way as with other fruit trees, and at the same season when the bark is sufficiently matured and is easily raised from the wood. The same stock can be made to bear one or several varieties. In the latter case, the effect is sometimes very singular, especially if different kinds are associated; for instance, Gooseberries and Currants of various colours, white, yellow, pink, green, red, and even black. At the beginning of last summer the nurseries of MM. Cronx et Fils, Vallée d'Aulnay, à Sceaux (Seine), contained a certain number of *Ribes palmatum*, which had been trained in single upright stems and budded as above described. Not only was their ornamental effect very striking, but they also possessed considerable interest. There seemed to be such a complete identity of constitution between the stock and the scion that in many cases the point where the bud had been inserted was hardly distinguishable. This was especially noticeable with the Gooseberries, which seemed to make one with, and only to be a continuation of, the *Ribes palmatum*—a fact which somewhat surprised M. Carrière; for, *à priori*, he would have expected the contrary. He therefore urges amateurs to put this mode of budding in practice; and, for that purpose, to rear as tall as possible single stems of *Ribes palmatum*, so as to produce tree Gooseberries and Currants, which will make remarkable rarities, especially the former. Nevertheless, it should be observed that as *R. palmatum*, *aureum*, *teuifolium*, and others, have naturally a great tendency to throw up suckers, especially when grafted or budded, care must be taken to remove all such suckers immediately that they show themselves. Another ornamental way of growing Gooseberries and Currants is to train them over a low arcade or bower. The ripe fruit, of various colours, hanging overhead, makes both a novel and pleasing addition to the foliage of such an arbour or covered walk. E. S. D.

ENGLISH NAMES OF WILD FLOWERS AND PLANTS.*

EIGHT years ago I was piloting a famous botanist from the east of England among the fields and lanes round Taunton, when he asked me the name of a plant which he did not at the moment recognise. I answered that it was the Gipsy-wort, and received a prompt rebuke. "This is the third time," he said, "that I have inquired the name of a flower, and you have answered me in English. The Latin names are universal, the English at best are local. It is to be wished that all English names of plants could be forgotten, and their scientific names become popularised instead." Unquestionably a foolish utterance, it was of great service to myself, for it set me to consider the real value of these names which my pedantic guest despised, and from that time to this I have never encountered the popular name of any English wild flower without questioning it closely as to its etymological history and meaning, and noting the passages in our literature where it occurs. It would be a great pleasure to me to believe that the knowledge gained by these inquiries, put together to the best of my power, could interest you to-night as much as it has interested myself.

It is no new thing to infer from the terms in use at the beginning of a nation's history the arts and customs of the nation using them. Thus the fact that in all or nearly all the Aryan languages the words for the Supreme Being, for the king, for brother and sister, for ploughing, grinding, building, closely resemble one another, is admitted to show that our common forefathers in times when they were still one people, and had not yet scattered into India, Persia, Europe, had the beginnings of religion and government, possessed the family life, knew the simple arts which are most needed for the comfort of home life. Let us see what light will be thrown upon the habits of our Teutonic forefathers if we apply their method of investigation to the popular names of plants.

TEUTONIC NAMES.

The following words are common to all the Teutonic languages—must have been known, that is, to the race from which we ourselves, with the Germans, Danes, Swedes, and Norwegians, are descended, on their first settlement in Europe, and before they broke up into sub-divided nations. The first I will take is Birch, the rind of which must, we

* Lecture by Rev. W. Tuckwell before the Somersetshire Archaeological and Natural History Society.

find, have been used for boat-building and for roofing houses; for boat-building, since the word "bark," from the same root as Birch, stands for ship in English, Dutch, Icelandic, Danish; for roofing houses, since the old English *beorgan* and the German *bergen*, also from the same root, mean to cover, protect, or shelter. From this simple word, then, we gather that our ancestors possessed the arts of building boats and of roofing or thatching houses. Houses could not be built without timber, and we find the word "tree" in almost every Aryan language standing for three things—for a tree, for timber, and for an Oak, extending the use of Oak wood for building purposes back to the first formation in Asia of our mother language, and presenting us with the additional facts that our European ancestors built of Oak timber the houses which they roofed with Birch. In Hazel a fresh fact lies buried. It is in all Germanic dialects the instrumental form of *has*, command or behest, a Hazel stick having been used, as Jacob Grimm informs us, in the earliest times as a sceptre or baton to keep order among slaves and cattle. Without dwelling on the fact that the old word *halsian*, to foretell, indicates the use of the Hazel rod for purposes of divination, we have the additional probability revealed in a single word that our remote ancestors possessed slaves and cattle. In Hawthorn, common to Swedish, German, and English, we have testimony to the use of a haw, *hæg*, hedge, or fence, "honouring the holy bounds of property," and consequently to the division and appropriation of land, in the earliest Teutonic time. My next word makes some demand upon your etymological credulity. Without tracing particulars, I will ask you to believe that the Sanskrit *Kshi*, to dwell, passes through various forms in one direction to the English "home," in another to the word "heath"; now meaning the plant which grows wild on open land, standing originally for the land itself. "My foot," says Rob Roy, "is on my native heath;" and the same idea was enshrined in the same word to the first Teuton settlers. In the forest he fought his enemies, hunted his prey, hewed timber for his fences, and peeled timber for his roof; his home was in the open land, or heath, from which, again, when ages had passed away and Christianity possessed the towns, he still worshipped his father's gods upon his father's heath, and gained, as Trench thinks, his ancient name of heathen. A sixth word lifts him higher than all the rest. The word Beech, in Gothic, old High-German, modern German, Norse, Danish, Dutch, English, is identical with book, the Runic tablets of our ancestors having been carved upon this wood. In Sloe, the wild Plum, we have the root of "slay," its tough wood having been used for bludgeons; Dog-wood is dagger-wood, from *dag*, to strike; from Ash, whose wood was therefore used for spear-shafts, came the old English *æs*, a spear; sedge is allied to *sæg*, a sharp small iron sword. And let us observe that while all these plants, bearing purely Teutonic names, extend far into Northern Asia, trees which stop short at a more southern limit—the Elm, Chestnut, Holly, Sycamore, Plum, Pear, Peach, Cherry—all have Latin names, showing that the Teuton squatters came from a colder country than that in which they are supposed to have settled near the Roman provincials on the Lower Rhine. The knowledge that Wheat, Barley, Oats, Corn, Rye, are all Teutonic words, completes the historical picture given by the first list of names. They show us a race of men coming from a northern to a southern region, dwelling in timber houses, roofed and thatched, launching boats upon the rivers, possessing cattle and slaves, recognising the rights of property and the sacredness of home, fighting with cudgels, swords, and spears, familiar with cereal agriculture, in some way not ignorant of letters. All these facts, just hinted at here, but challenging minute investigation, we owe to a dozen common names of English plants, whose Latin equivalents teach and commemorate nothing of any national interest to ourselves.

GREEK AND LATIN NAMES.

These names, and a few more, are as old as the English language; but from the conquest to the sixteenth century botanical enquiry ceased in England, and the rest of our popular names are little more than 300 years old. Most of these come to us from the Greek and Latin. Any scholar will detect in *Acacia* the Greek word for guilelessness; in the *Amaranth*, with which Milton's worshipping archangels wreathed their brows, the Greek for

unfading; in the *Periwinkle* the *peruinca* used to bind about the head; in *Lettuce*, the meaning of milky; in *Geranium*, the descriptive name, crane's bill. In the *Plane* he will see the *platanus* of the poets; in the *Rose*, the *rhodon* of Homer and the *rosa* of Virgil; in the *Sycamore*, the wild Fig of the Bible, transferred in mediæval miracle-plays to the tree which now bears the name; in the *Vine*, the *oinon* and *vinum*, whose Sanskrit root is still present in our words twine and twist. He will understand that the *Basil*, which poor simple Isabel planted in the pot which held her murdered lover's head, was the regal plant, used perhaps of old in some royal bath or unguent; that the *Angelica*, which now flavours our soups, and was once a specific against the plague, was given to mankind by angels; that the *Belladonna* was applied as a cosmetic to make ladies beautiful for ever; that the *Cyclamen*, which still grows wild in Devonshire, owes its name to its prominent circular tuber. He will not so readily discover that the Tansy of our cottage gardens is the Greek *athanasia*—immortality, administered to *Ganymede* that he might become fit for his life in heaven; that the common *Milfoil* Yarrow is the *hierac*, or holy herb, pledged to heal all herbs with its fragrant leaves; that *Nasturtium* means nose-twister, from its pungent smell; that our *Quantoek* *Whortle-berry* is a corruption of *myrtillus*, *Myrtle-berry*; that *Eglantine* is *aculeata*, the prickly *Rose*, or *Sweet Brier*; that the *Herb Bennett* or *avens*, is the *benedicta*, blessed herb, kept in houses to prevent the entrance of the Devil; that the *hip* of the *Dog Rose* is a form of the Greek and Latin words which people afflicted with sore throats know as *jubes*; that *Liquorice* is an Anglicism of the Greek *Glycyrriza*, sweet-root; that the *Larch* is from the Latin *lar*, a house, in consequence of its use in building; that *Lavender*, from the Latin *lavare*, to wash, was in the twelfth century Scotch and northern English for washerwoman, because then as now its sweet spikes were laid amongst fresh linen; that the *Service-tree* is the Latin *cerevisium*, beer—its leaves having been used to flavour ale before the virtues of the *Hop* were known; that the little *Squinancy-wort* was the ancient remedy for the disease *lynanche* or dog-choker, which we know in its modern sound as *quinsy*; that the *Mushroom* is the *Muscarius* or *Fly-bane*, because a particular *Agaricus*, pulverised and mixed with milk, was used in Southern Europe as we now use the poison called "Keating's Insect Powder." Least of all will our scholar be quick to admit that the *Narcissus* owes nothing to the love-sick youth over whom *Ovid* sung and *Bacon* moralised, but is connected with the Greek *narkodes*, sluggish, a derivative from *narkê*, the torpedo, itself sprung from the Sanskrit *nark*, hell; cited by *Sophocles* (Ed., Col., 682), as crowning the gods of *Hades*; gathered by *Proserpine* before her wedding tour into the same dark region, because its heavy odour (for by it the ancients meant the *Hyacinth*) blunts the nerves and makes men sleepy and torpid.

FRENCH NAMES.

I can find comparatively few names which we have borrowed from the French. *Dandelion* is, of course, the lion's-tooth. *Mignonette* is applied by us to a very different plant from that which bears the name in France. *Woodruffe*, known to travellers in Germany as flavouring the pleasant drink called *maitrank*, takes its last syllable from *roue*, a wheel, its verticillate leaves being set like a wheel or rorwell on the stone. *Pansy* is *pensée*, thought, from its significance in the language of flowers: "There's *Pansy*," says *Ophelia*—"that's for thoughts." *Gilliflower* is *giroflée*, from *caryophyllum*, a Clove, a name originally given to the *Carnation*, but now transferred to the *Wall-flower*. *Tutsan* is *toute-saine*, the oil in its leaves having made it a remedy for wounds. Most curious of all is *Apricot*, from *abricot*, which at one time I contentedly referred to the Latin *apricus*, sunny, ripening as it does on sunny walls. It is, in fact, traceable to the Latin *præcox*, early, the fruit being supposed by the Romans to be an early *Peach*. The Arabs took the Latin name and twisted it into *al buquq*; the Spaniards altered its Moorish name into *albaricque*; the Italians reproduced it as *albicocco* the French as *abricot*, and we get it next in England curiously enough as *Apricock*, so spelt in Shakespeare's time, and finally as *Apricot*.

LEGENDARY NAMES.

Many curious bits of myth and history reveal themselves as we excavate down to these old meanings. The *Priony*, or healing-plant, commemorates the

Homeric god *Præon*, the first physician of the gods, who tended the bellowing *Ares* when smarting from the spear of *Diomed*. The *Centaur* is the plant with which the centaur *Chiron* salved the wound inflicted by the poisoned arrow of *Hercules*. The *Ambross*, or *Wormwood*, is the immortal food which *Venus* gave to *Aeneas*, and *Jupiter* to *Psyche*—the Sanskrit *amrita* which *Kebama* and *Kailya* quaff in Southey's splendid poem. The *Anemone*, or *Wind-flower*, sprang from the tears wept by *Venus* over the body of *Adonis*, as the *Rose* sprang from his blood—

ἀνα ὄσδου τέρει, τὰ δὲ δακρυὰ τὰν ἀνεμόναν.

The *Daphne*, *Syringa*, and *Andromeda* tell their own tales: the last, which you may find in the peat-bogs round *Shapwick station*, is due to the delicate fancy of *Linnaeus*, who first discovered and named it, blooming lonely on a barren, rocky isle, like the daughter of *Cepheus*, chained to her sea-washed cliff. The *Juno Rose*, or tall white *Lily*, was blanched by milk which fell from the bosom of *Juno*, the tale being transferred in Roman Catholic mythology to the *Virgin Mary* and the *Milk-Thistle*. The yellow *Carlina Thistle* is named after *Carl the Great* (in Mr. Freeman's county I must not call him *Charlemagne*), who, praying earnestly for the removal of a pestilence which had broken out in his army, saw in vision an angel pointing out this plant as a heaven-sent cure. The *Herb Robert* healed a disease endured by *Robert, Duke of Normandy*, still known in Germany as *Rufrecht's-plage*. The *Filbert*, though this is disputed, commemorates the horticultural skill of one *King Philibert*. The *Treacle Mustard*, a showy crucifer resembling *Wallflower*, was an ingredient in the famous *Venice treacle*, compounded, as you will remember, by *Wayland Smith* to treat the poison sickness of the *Duke of Sussex*. The word *treacle* is corrupted from the Greek *theriacum*, connected with wild beasts, whose blood formed part of the antidote. It was at first made up by the physician to *Mithridates*, king of *Pontus*, and is still in many parts of England known as *Mithridate Mustard*. The *Flower-de-luce*, or *fleur-de-lys*, is the flower of *King Louis*, having been assumed as a royal device by *Louis VII.* of France, though legend figures it on a shield brought down from *Heaven* to *Clovis*, when fighting against the *Saracens*. It is probably a white *Iris*.

Not a few strange superstitions and beliefs are embalmed in well-known names. The *Celandine*, from *cheldion*, the swallow, exudes a yellow juice, which, applied by the old birds to the eyes of young swallows, who are born blind, or have lost their sight, at once restores it. The *Hawk-weed* has the same virtue in the case of hawks. The *Fumitory*, *fume-terre*, was produced without seed by smoke or vapour rising from the ground. The *Devil's-bit* is a common *Scabious*, with a premore or shortened root, which was used so successfully for all manner of diseases, that the *Devil* spitefully hit it off, and for ever checked its growth. The *Eyebright*, or *euphrasy*, was given to cure ophthalmia.

"Michael from Adam's eyes the film removed,
Then purged with euphrasy and rue
The visual nerve, for he had much to see."

The *Judas-tree*, with its thorns and pink blossoms, was the tree on which *Judas* hanged himself. The *Mandrake* gathered round itself a host of wild credulities. It was the *Atropa Mandragora*, a plant nearly allied to the deadly *Nightshade*, but with a large forked tuber resembling the human form. Hence it was held to remove sterility, a belief shared by *Rachel* in the *Book of Genesis*, and was sold for high prices in the middle ages with this idea. In fact, the demand being greater than the supply, the dealer used to cut the large roots of the *White Bryony* into the figure of a man, and insert grains of *Wheat* or *Millet* in the head and face, which soon sprouted and grew, producing the semblance of hair and beard. These monstrosities were fetched in Italy as much as thirty gold ducats, and were sold largely, as *Sir T. Brown* tells us, in our own country. It was thought that the plant would only grow beneath a murderer's gibbet, being nursed by the fat which fell from his decaying body: hence it formed an ingredient in the love-philtres and other hell-broths of witches, and, as it was believed that the root, when torn from the earth, emitted a shriek which brought death to those who heard it, all manner of terrible devices were invented to obtain it. The readers of *Thalaba* will remember the fine scene in which the witch *Khawla* procures the plant to form part of the waxen figure of the *Destroyer*. I have seen the plant growing in the *Cambridge Botanical Gardens*; it is not uncommon in *Crete* and *Southern Italy*; its fruit is narcotic, and its name is probably derived from *mandra*, an enclosed, over-grown place, such as forms its usual home. *Nature*.

(To be continued.)

DUTCH BULBS.

THROUGH the kindness of Messrs. Byvoet, of Haarlem, we are enabled to give a list of the Hyacinths and Tulips which formed part of their prize collections at the Amsterdam International Horticultural Exhibition in the spring of the present year. The list may be of some interest to those who are about purchasing bulbs. The varieties marked * formed also part of the smaller collections, and may therefore be looked on as superior varieties for exhibition purposes.

COLLECTION OF 100 FLOWERING HYACINTHS IN POTS IN 100 VARIETIES, SIXTY SINGLE AND FORTY DOUBLE.

Single Red.	Single Blue.	Double Red.
Fabiola, or Florence	Czar Peter	Princess Royal
Nightingale	Lord Derby*	Belle Alliance
Romeo	Mary of Scotland	La Jeune Christine

AUTUMN ROSES.

BEFORE the season for purchasing comes round, a few words about the most valuable of all Roses—those which bloom freely in the autumn—will not be without benefit to the large class of amateurs who have little opportunity of making observations for themselves. An authentic list of such varieties will not only form a basis for additions to collections, but also serve to correct notes taken at the summer shows, which afford no criterion of the perpetuity of the kinds staged on such occasion. For these reasons the kinds here given are chiefly those which have already appeared, and which have again occupied a noteworthy position in the stands where Roses have formed a portion of the exhibitions in the later part of the year. It is surprising how many of the so-called perpetuals are in actual culture, virtually only summer Roses, their second crop being either nothing, or of

such inferior quality as to be scarcely worth growing at all except for the earlier exhibitions. It is unfortunate also that fragrance appears to be as little valued by many of the raisers of modern Roses as true perpetuity. Some of the most attractive Roses of modern date, Baroness Rothschild for instance, are destitute of that property which is, so to speak, almost the very soul of the Rose. We may almost exclude the "Teas" from comment, as they are always late bloomers, some perhaps a little more freely so than others, but all worth cultivating are essentially autumn bloomers, the difference being that some display that invaluable function out-of-doors and with greater perfection in colour and substance than when grown under glass. The whole of the Gloire de Dijon family, which bid fair to become a distinct race, are remarkable for this faculty. Madame Berard and Belle Lyonnaise with the Gloire itself are never so rich and so fine as late in the year.

The following were well shown at the Alexandra on September 13, though the boxes were much less numerous than they otherwise would have been but for the heavy rains in the earlier part of the week. They may, therefore, be taken as representing good autumn bloomers, and consequently worth the particular attention of those wishing to add to or remodel their collections. We shall give them alphabetically, for the sake of convenient reference:—

Abel Grand, H.P.	Madame la Baronne Rothschild, H.P.; one of the most numerous illustrated, and in fine condition.
Adrienne Clotopole, T.	Madame Bellenden Kerr, H.P.
Alba rosea or Madame Bravy, T.	Madame Marie Finger, H.P.
Alfred Colomb, H.P.; frequently, and in fine form.	Madame Trifle, T.
Antoine Ducher, H.P.; a bloom or two.	Mdlle. Annie Wood, H.P.; several good.
Auguste Rigotard, H.P.; ditto.	Madame Victor Verdier, H.P.; most excellent.
Beauty of Waltham, H.P.; several, in fine order. It is remarkable how frequently this fine old Rose appeared in the prize boxes at the great summer shows, inconceivably proving its superior merit.	Mdlle. E. Verdier, H.P.; good.
Belle Lyonnaise, T.; very frequently.	Marie Rady, H.P.; good.
Bessie Johnson, H.P.; more than once.	Marçal Niel, T. or N.; not particularly fine.
Bouquet d'Or, T.	Marie Baumann, H.P.; frequently shown, and well.
Captain Christy, H.P.; whatever other faults it may have it must certainly be admitted a free bloomer in the autumn.	Marie Van Houtte, J.
Céline Forestier, N.; some blooms of this.	Marquis de Ligurieres, H.P.
Charles Lefebvre, H.P.; not so fine as some.	Marquise de Castellane, H.P.
Cheshunt Hybrid, T.	M. Hassard, H.P.; good.
Comtesse d'Oxford, H.P.; several times.	Maurice Bernardin, H.P.; a fine bloom or two.
Dr. Andry, H.P.	Paul Néron, H.P.; more double and symmetrical than usual, in consequence of not being overdone. The writer cut a bloom of this in Mr. John Fraser's nursery a few days before the show, almost equal in globular form to Felix Genero.
Duke of Edinburgh, H.P.; frequently and fine.	Mons. E. V. Teas, H.P.
Dupuy Jamin, H.P.	Narcisse, T.; always a good autumn bloomer.
Emile Hausberg, H.P.; fine and globular.	Nightingale, T.; some good specimens appeared.
Etienne Levet, H.P.; many times and good.	Perle des Jardins, T.; a nice yellow Tea.
Ferdinand de Lesseps, H.P.	Prince C. de Rohan, H.P.; a bloom or two.
Fisher Holmes, H.P.	Princess Beatrice, H.P.; several very fine examples.
François Michelon, H.P.; good.	Sir Garnet Walseley, H.P.; in Mr. Grant's stand were some good flowers.
Général Jacqueminot, H.P.; one of the most floriferous and continuous of all the H.P.'s.	Malmaiton, B.; always a fine late Rose.
Gloire de Dijon, T.; plentiful and good.	Rev. J. B. M. Camm, H.P.; good.
John Hopper, H.P.	Star of Waltham, H.P.; many fine examples, proving amongst other excellencies that it is a reliable late Rose.
La France, H.P.; most numerous of any kind.	We cut some much finer specimens at the Waltham Cross Nurseries, however, than were seen at the Palace.
Louis Van Houtte, H.P.; plentiful and good—far before Reynolds Hole, the few blooms of which, together with the Duke of Connaught, presented a burnt and foxey appearance at the petal points—anything but attractive.	Victor Verdier, H.P.; a well-known autumnal bloomer.
Madame Berard, T.; many superb examples.	Von Moltke, H.P.; not often exhibited, though small, of a brilliant colour.
Madame Charles Wood; good.	Xavier Olibo, H.P.; very rich, but scarcely a Rose for amateurs unless under exceptionally favourable conditions.
Madame Falcot, T.	
Madame George Schwartz, H.P.	

It must not be supposed that these names exhaust the list of good autumnal Roses, or that others could not be found to accompany them at the nurseries or in large collections. There are hosts of old favourites of well established repute that have been and will be in flower till cut off by the frost. There is another reason given as an illustration derived from the last public displays, which have had everything against them from unfavourable atmospheric conditions—the feasibility of establishing autumnal Rose shows. Under ordinary circumstances the list would have been multiplied fourfold, but exhibitors are notoriously at the mercy of the weather.

Speaking generally the present can scarcely be termed "a Roseless autumn." In this respect the

writer has met with few complaints. The writer's personal observation at several large nurseries, as well as at private collections, corroborates this view. There has been no lack of fine flowers, with promise of plenty more to come, Jupiter Pluvius and rude Boreas—"blustering railer," as the song says—permitting. *W. D. Prior.*

FOREST TREES OF CANADA.

(Concluded from p. 299.)

Acerineæ.—Two of these trees are very common all over Canada, the Rock Maple (*Acer saccharinum*), and the White Maple (*A. dasycarpum*). These are the most beautiful trees in the Canadian forest. Their tall rugged trunks are crowned with a mass of foliage, beautiful in summer, but doubly beautiful when turned by the early frosts of the fall into twenty gorgeous colours and shades of colours. My pen is quite unable to describe the beauties of the Canadian forest at this season of the year. No painter has ever done justice to it. The Rock Maple is a very tough, close-grained, and hard wood. It is highly prized for axe-handles, sleigh-runners, shafts, poles, machinery, and any purpose for which strength and elasticity are required. The Bird's-eye Maple that we see in furniture and ornaments is merely a variety of the Rock Maple, so is the Curly Maple. The woodsman never knows before he strikes his axe into the tree whether it is bird's-eye, curly, or plain.

The Rock Maple is the tree from which the maple sugar is made. Early in the month of April, in Lower Canada, when the snow is still deep in the wood, the inhabitants, the Indians, and many of the back settlers hie into their sugar camps; sometimes accompanied by their wives and families, who enjoy the picnic immensely. The sugar-maker provides himself with a large quantity of Birch-bark sheets in the summer, which he makes up into troughs or pails to hold the sap. Some hundred of these are required in a large "sugary." The Maple tree is tapped by cutting the letter V in the bark. At the angle a little peg of wood is stuck in, to act as a spout, and convey the sap into the trough which is placed below it. A good tree will yield 3 gallons of this sap in a day. The sap only runs in warm sunny days after frosty nights; 4 gallons of this sap are required to make 1 lb. of sugar. It is boiled down in a cauldron over a hot fire until the syrup on being dropped into the snow turns hard. When it is sufficiently boiled it is strained through a blanket (let us hope a clean one), and poured into bark dishes, when it soon hardens. The boiling and straining is the work of the women; the men are kept very busy in attending to the trees and collecting the sap. One man will sometimes tap 200 or 300 trees. An Indian, with his wife and little child, can make 600 lb. of maple sugar in one spring. A very good Maple tree in one season will yield 8 lb. of sugar. Some springs the sap runs better than others. Strange to say, this great depletion—8 lb. of sugar represents about 32 gallons of sap—does not seem to hurt the tree, which is tapped season after season without any bad result to its health. The average run of large trees is about 20 gallons in the season.

The stranger is astonished to see this very ornamental and useful timber used as firewood. Rock Maple is the best of fuel, and constitutes the staple firing of Lower Canada, New Brunswick, and Nova Scotia. Hundreds of thousands of trees are burned every winter. Many thousand stoves in Lower Canada alone glow all winter with red-hot Maple brands, and yet they make no perceptible difference in the Maple forests. With fair play the Maple and the other valuable woods in the Canadian forests will suffice not only to warm and to shelter many generations of Canadians yet unborn, but also to adorn and beautify their country for ages to come. Detestable forest fires, the result of gross carelessness, do more harm to the forests in twelve hours than all the stoves in Canada do in a year. The Rock Maple indicates good dry soil, and is generally found growing with Beech, Black Birch, and White Maple. The White Maple is an equally ornamental tree, but the wood is inferior both as timber and as fuel. There are also two or three other varieties of the Maple, one of which, *A. pennsylvanicum*, is the favourite food of the moose.

Cupulifera.—The White Oak (*Quercus alba*) occurs here and there in the lower provinces, but is abundant in Canada West. It is a large and valuable tree, indi-

cating the best quality of land. The wood is made into staves, and is used for carriage building and other purposes. The bark is used in the tanneries. The Swamp Oak (*Q. prius*), a variety of the above, so called from its growing in swampy places, is also an excellent and very tough wood. The Red Oak (*Q. rubra*) is a somewhat inferior wood to both of these.

The Beech (*Fagus sylvestris*) is common all over Canada, and is generally found in company with the Maple and the Birch. It is a hard and excellent timber, but not much lumbered. Together with Maple and Birch it is cut up in 4-foot lengths, split, and piled in little heaps 8 feet long by 4 every other way. In this shape it is called cordwood, and is sold

Black Ash (*F. sambucifolia*) grows in swamps. It is chiefly used by the Indians for basket making. A tree is cut down, and after having been macerated in water it is beaten with the poll of an axe until the wood peels off in narrow ribbons, which the Indians dye and weave into baskets. Ash trees of both kinds indicate a poor soil.

Ulmaceae.—The White Elm (*Ulmus americana*), a magnificent tree, that grows in rich intervalle lands, generally near the banks of rivers or creeks.

The Rock Elm (*Ulmus racemosa*) grows chiefly in Canada West, in the same sort of land as the foregoing. Both these Elms are very valuable wood.

Tiliaceae.—Basswood (*Tilia americana*). A very

more open in the grain, but makes very pretty furniture. The nuts are like Walnuts in shape, only much harder in the shell and the fruit more oily, not unlike the Brazil nuts in flavour. A very pretty tree; grows in poorer soil than the Walnut.

The Hickory (*Carya alba*) is the heaviest of all Canadian woods. Used for tool-handles, carriage-spokes and shafts, fishing-rods, &c. There are two varieties of this tree, the rough-bark and smooth-bark. Grows only in Canada West. The nuts of the rough-barked variety are very good eating.

Anacardiaceae.—Sumac (*Rhus typhina*). A small and very pretty tree, that grows chiefly in succession to the first forest crop. Indicates bad land. The

FIG. 73.—RAIN-GAUGE AT ROTHAMSTED; AREA, ONE-THOUSANDTH OF AN ACRE.

as fuel. The Winter Beech is a variety so called from its retaining the dead leaves all winter. It is a small tree, but the wood is much valued for axe-handles and agricultural implements.

The Chestnut (*Castanea vesca*). This tree grows only in Canada West. The wood is light and durable. It is very like our own Chestnut, if not identical; the nuts are much alike.

The Hornbeam (*Ostrya virginica*) is one of the hardest of Canadian woods. It is a small-sized tree; the wood is used by carriage builders.

Oleaceae.—White Ash (*Fraxinus Americana*) grows in low land. A very tough and flexible wood, of closer grain than the English Ash. It is found all over Canada; used by carriage makers, barrel makers, &c. It is the most flexible of Canadian woods, and is used for making hoops, also by the Indians for making snow-shoe bows.

soft wood, something like our Sycamore; useful for turning and carving; also used in furniture and machinery.

Salicaceae.—The American Poplar, Aspen, or Popple (*Populus tremuloides*). This tree is commonly found occupying the place of the old Pine forests that have been destroyed by fire. It is a very soft wood, of not much value. The Balm-of Gilead is a variety of the above. The seed coverings of this tree are a sort of down or cotton, which falls in the summer like snow.

Juglandaceae. (Not found in the northern forests.)—The Black Walnut (*Juglans nigra*) grows only in Canada West. A very valuable wood, used chiefly by furniture makers; also makes stocks of guns, &c. Well known in this country.

Butternut (*Juglans cinerea*). This is an inferior species of Walnut, the wood is lighter in colour and

wood is of a yellow colour, and used for furniture and dyes. The bark is valuable for tanning purposes. The seed is contained in large crimson pods, which makes the tree very gay in the fall of the year. The Sumac is a very pretty ornamental tree, and grows freely when transplanted.

Amygdaleae.—There are three Cherries, of which the Red Cherry (*Cerasus pennsylvanica*) and the Choke Cherry (*C. virginiana*) are the most common. The former is one of the first trees that springs up on burnt land in succession to the Pine and Spruce. In some districts in the early summer whole tracts are white with the blossom of the Red Cherry. The fruit is not good. The Black Cherry (*C. serotina*) is a larger tree, and the wood is of some value, also the fruit. It only grows in Canada West. The Choke Cherry, so called from the fruit, which is such a strong astringent as almost to choke the eater. This pretty shrub grows in the outskirts of the forest.

Natural History.

THE WAGTAIL AND THE CUCKOO.—In your issue of the 1st I find an account, from your correspondent, Mr. Thomas Wynne, of the rearing of a young cuckoo by a pair of water-wagtails which had built their nest in a Laurel bush. Mr. Wynne states that he never before knew that these birds built in shrubs; I also was ignorant of the fact of water-wagtails building in shrubs, although I have paid some attention to the habits of our commoner birds. Some weeks ago, however, at the house of a relative, I saw a wagtail's nest built in a fork of the Cotoneaster microphylla, which covered the front wall of his house. The nest was about 2 feet from the ground, and not more than that from the portico. Here, close to the main door of the house, a pair of young wagtails were reared, and in due time took to wing. Though exceptional, I have little doubt that others of your correspondents will be able to cite a few similar instances of departure from usual habits. *J. A. C.*

THE CUCKOO.—In reply to "W. E. T.," in the issue of September 8, regarding the habits of this bird, I confidently believe they do suck the eggs of various species of the feathered tribe. I have found many nests during the past few seasons thus destroyed, the eggs being in many instances broken open in a manner which left no doubt that it had been done by the beak of some bird. Now in this immediate neighbourhood we have neither jays, squirrels, nor snakes, which "W. E. T." thinks might be the culprits; but both cuckoos and magpies are very plentiful, and it is known that the latter of these birds will destroy eggs. Having studied the habits of birds for years, I am convinced that both the above birds destroy many nests during the breeding season. There is no doubt that the habits of the cuckoo are not yet fully known, more particularly during the breeding time; but those naturalists who daily see these birds in their haunts during the spring may eventually, by careful study, solve many things which are at present open to much doubt concerning the cuckoo. *York-shire.*

PLANT PORTRAITS.

ALLIUM UNIFOLIUM, *Bot. Mag.*, t. 6320.—A handsome Californian species resembling *A. roseum*, but differing from all known species by the circumstance that its bulbs are developed at a distance one from the other, and are connected by a thread-like rhizome. The plant was introduced by Messrs. Backhouse.

DENDROBIUM CRYSTALLINUM, *Bot. Mag.*, t. 6319.—A species described in our columns, 1868, p. 572. Like *D. Wardianum*, to which it is closely allied, it is a native of Birma; it differs from it by the shape of its elongated anther-case, which is covered with very prominent crystalline papillae. The plant was discovered by Colonel Benson, and was introduced by Messrs. Veitch.

ESCHSCHOLTZIA MANDARIN, *Floral Magazine*, t. 275.—A splendid variety of the common *Eschscholtzia*; the petals are clear yellow within, but blood-red on the outer side. Carter & Co.

ODONTOGLOSSUM CIRRHOSUM, Lindl., *Bot. Mag.*, t. 6317.—A very beautiful *Odontoglossum*, with dense panicles of white flowers, the lance-shaped segments spotted with brown, and with a yellow lip. Native of Ecuador, and figured by us in 1876, p. 503.

ORANGE, TANGIERINE, *Florist*, September, 1877.—A good figure of the fruit of this fine variety, from the collection of Messrs. Rivers.

PAVONIA WOODII, *Floral Magazine*, t. 276.—A stove shrub of the Mallow family, with lanceolate-serrate leaves; the flowers are each provided with an outer calyx of numerous linear pink or red bracts forming a kind of cage over the true calyx.

PELARGONIUMS ARTIST, EVELYN, DESPOT, *Floral Magazine*, t. 273.—Three show varieties, raised by E. B. Foster, Esq., Clewer Manor, Windsor, and in the hands of Mr. Turner, of Slough.

PELARGONIUM PRINCESS OF WALES, *Florist*, September, 1877.—One of the new Regal *Pelargoniums* sent out by Mr. W. Bull. The flowers are large, the petals crisped and frilled at the edges, the disc of the petals of a bright rose, mottled with white spots, and with a white stalk. The two upper petals are blotched with maroon.

PITCAIRNIA FLAVESCENS, *Bot. Mag.*, t. 6318,—

A stemless Bromeliad, with long, sheathing, recurved linear-lanceolate leaves, whitish on the under surface, erect, many flowered racemes, with a woolly rachis and pale yellow spreading flowers each about 2 inches long. The native country is not known. The present plant flowered at Kew in April.

PINK DUCHESS, *Floral Magazine*, t. 273.—A forcing Pink of lilac colour and good form and substance. It is in the hands of Mr. B. S. Williams.

PINK, SCARLET TOM THUMB, *Floral Mag.*, t. 270.—A very dwarf, stiff-habited Pink, with large, well-formed, fragrant, scarlet flowers. It was introduced by Messrs. Veitch, and is certainly a most desirable plant for pot culture.

ROSE EDWARD PYNBAERT, *Revue de l'Hort. Belge*, September, 1877.—A fine globular Rose, of a bright red-groseille colour. It is a seedling from Antioie Ducher, raised by M. Schwarz, of Lyon.

SONERILA ALP. VAN DE SANDE, *III. Hort.*, t. 229.—A form with ovate-lanceolate leaves of a rich deep green colour abundantly blotched with irregular creamy white spots.

SPIRÆA VENUSTA var. **ALBICANS**, *Revue de l'Horticulture Belge*.—A chance seedling from *S. venusta*, found in the nurseries of Simon-Louis, near Metz. It differs from the type in its lighter rose-coloured flowers.

TRADESCANTIA NAVICULARIS, Ortgies, *Gartenflora*, t. 901.—A creeping species, with small, boat-shaped ovate-acute leaves, and small pink flowers. It is a native of Peru, and would make a pretty greenhouse basket plant.

TULIPA KAUFMANNIANA, Regel, *Gartenflora*, t. 906.—A species with medium-sized flowers, with oblong obtuse segments of various shades of pink, and with a yellow base. The anthers open gradually from above downwards, so that the upper portion is withered while the lower part is still unexpanded—a very curious circumstance. The plant is a native of the mountains of Turkestan.

TULIPA ORPHANIDEA, Boiss., *Bot. Mag.*, t. 6310.—A Greek species, discovered by Dr. Orphanides, with flowers as large as those of *T. silvestris*, of an orange-yellow colour, flushed with red. Figured from a plant which flowered in June in the garden of the Rev. H. H. Crewe. We do not understand how the termination *ea* was arrived at for this species, and leave it to the grammarians to explain.

YUCCA ORCHIOIDES, *Bot. Mag.*, t. 6316.—A form intermediate between *Y. orchioides* of Carrière and *Y. filamentosa*, being probably an extreme form of the latter species. In any case, with its broad spreading leaves with filiferous margins, and its panicle of large white, spreading, bell-shaped flowers, it is a very handsome, hardy plant, worthy of a place in every garden. The plant figured bloomed at Kew in July.

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—Stock of all winter-blooming stove plants, especially such as are of a soft character, annually propagated, must not be left too long in pits or similar structures where they cannot receive enough warmth, for even in cases where they are not required in flower until the end of the year they must not be subjected to too cool treatment, or their roots will be liable to either perish or become stagnant to an extent that will seriously injure their blooming capabilities. *Salvia*, *Sericographis*, *Begonias*, and a portion of the *Poinsettias* should now be kept tolerably warm to bring them into flower at the time required.

Ferns.—There is one circumstance often lost sight of connected with the cultivation of heat-loving plants—*Ferns* in particular—that is, the rapidity with which that most troublesome insect, brown-scale, is communicated from any specimens which are affected with it, and which overhang others. The habits of this insect, which entails such an amount of labour in keeping it down, with injury and disfigurement to the plants, consequent upon the cleaning process they have to undergo, are little observed and often very little understood. From the apparently fixed position which it holds on the leaves and stems of plants, the observer is frequently led to the conclusion that it is little likely to be communicated to clean subjects, unless these are placed for a considerable time in absolute contact with affected ones; yet if any one will take the trouble to examine these scale coverings when they have attained something like their full size, if they are removed without crushing, it will be found that each contains a numerous colony of very small but perfectly formed insects, whose powers of locomotion will be easily

seen if placed upon a leaf or the hand, and subjected to a slight magnifying power. When these insects are released naturally from their scale-covered habitation very little disturbance of the plant, even no more than occurs from the use of the syringe, brings them down in quantity upon everything that stands beneath taller affected plants. In this way it often happens in the Fern-house that the most valuable dwarf-growing kinds, such, for instance, as *Gleichenias*, get seriously infested with the pest from overhanging Tree Ferns; consequently where scale exists in the latter the cultivator should not rest with merely keeping them in check, but ought to be satisfied with nothing less than their extermination. It is from now to the end of the year, when the season's growth has attained a mature hard condition and no young fronds are being formed, that the cleansing process may be effected with least injury. The lower, older fronds are those that are generally infested, and from these they usually find their way to the younger ones above, to prevent which many growers cut away the lower ones; but as the removal of the fronds in a green state has a serious weakening influence upon the plants, means should be taken to free them from the scale without cutting away until they have decayed naturally. When much affected, it is almost a hopeless task to attempt their complete eradication by brushing and sponging, as, even when the plants are repeatedly gone over, some are almost certain to escape detection. I have found nothing so effectual as, at this time of the year, immersing the infested fronds in Abyssinian Mixture at from 6 to 7 oz. to the gallon, varying the strength according to the more or less hardy state of the fronds, consequent upon the conditions under which they have been grown. The plants are awkward to get at for this purpose. I have found it best to lay them down on their sides, inclining the heads sufficiently to enable the affected fronds to be immersed in the mixture, in which position they should lie for an hour, turning the plants round until all the infested parts are so treated, when if the work is well done very few will escape; indeed, if there is any doubt, a second application should be given. At first sight this may seem to involve considerable trouble, but complete extermination will in the end be found a great saving of labour. Lower growing spreading Ferns that have now completed their growth may be similarly treated. With young plants of *Gleichenias* particularly, the work should be followed up until they are perfectly free from the insects, some of which often get so low down as to be found on the rhizomes creeping upon the surface of the soil. If these most beautiful and valuable Ferns are not effectually freed from this, to them the worst and most unmanageable of insects, before they attain any considerable size, the work becomes impossible so far as the ordinary cleaning by hand goes, as the incessant brushing and sponging renders them unsightly. *Adiantums*, *Aspleniums*, *Pteris*, *Polypodiums*, *Nothochlænas*, *Lomarias*, *Doodias*, *Davallias*, and similar dwarf-growing species should be treated in like manner, and the work persisted in until a thorough cleansing has been effected.

My reason for now going so far into detail in this matter is from a conviction that to see these most beautiful plants in the condition which they ought to be, they must be kept free from these, their worst enemies; and if, as happens in most collections, the plants are also more or less affected with thrips, the eradication of these at the same time is certain by the same means. It is useless, however, to attempt the work at any other time except now through the autumn, when most of the species will have done growing, and be devoid of soft immature fronds.

Previous to these insect-cleaning operations being carried out any plants that have ripe spores upon them, and which it is desirable to propagate, should have these taken off and sown. With many of the most difficult to raise in this way, if the spores are left until they can be shook off, it will be found the operation comes too late, and that they are already fallen and lost. I have found it better to take a few likely fronds, cut them in small bits with a pair of scissors, and strew them over the surface of the pans of prepared soil, squeezing them down by hand so as to be under the influence of the moisture contained in it. In this way I have increased many varieties with which I have previously failed. Seedling Ferns that have been raised through the summer should be now pricked off into well drained pans filled with very open porous soil, putting them in an inch apart; if allowed to remain through the winter in the seed pans they get weakened by over-crowding. Young Ferns that were moved singly some months back into thumb-pots should, as they require it, receive a shift, not giving them too much room; in this way they will be much better calculated to make strong growth next summer than if the potting was deferred until spring, as they will thus be enabled to acquire much more strength of roots. *T. Baines.*

ORCHIDS.—The very beautiful and showy varieties of *Miltonias* that will now be in flower, partly on account of their blooms appearing when there is a

comparative absence of flowers, and also because they retain their colour and freshness for a considerable length of time, are of such a useful and pleasing character that where convenience can be given it is desirable that they should be well reproduced and a little extra care given to them at all times. It is not always that they are to be met with in a very healthy and satisfactory condition—either the leaves are of a dull, yellow colour, with shrivelled bulbs, or in some cases the bulbs are without leaves altogether. In hardly any collection will the dwarf, compact-growing species, as *M. spectabilis*, *bicolor*, *virginalis*, or *Moreliana*, be observed where the foliage is of a deep shining green, and in these cases it is not so essential as an indication of health and vigour as it is with the majority of plants. These are all close and free growing species, and on account of the great numbers that have been imported at various times, are found to vary very much in different plants. Of *spectabilis* the labellum in some varieties is of an intense rosy purple, the colour being diffused to the very edge, the flowers also standing up in a very firm and bold manner. Among the *Morelianas*, too, are some where the flowers are of an unusual size and substance, the colour and veining of the lip being of a very rich and distinct character. These should all be grown in the Cattleya-house. As a rule they are found in their native habitat clinging very securely to the smaller branches of the trees, the small roots closely interwoven one over another, the growths at the same time gradually working themselves quite round the stems, forming close and dense tufts. They may be grown on blocks, in which condition they will root and grow very freely; in fact, if those that are just received after importation are treated thus they come on better than if they were made up in pots in peat and moss and stood on the side tables. On blocks they can be treated to copious supplies of water, and this during the lengthened growing season is an absolute essential; at the same time it runs quickly away, and thus the risk of damp and rot is not so great as when a mass of damp soil is present, and only a few roots entering it. When, after becoming established, it is thought desirable to make them up into larger specimens, they may be fixed, blocks and all, three or four, according to size, in shallow pans, so that they may be suspended from the roof. In making them up use plenty of drainage, and in the moss and peat some small crocks or broken pieces of bricks will be found to be of service in keeping the soil porous and open. At no season must they have the direct rays of the sun allowed to fall on them; at the same time a good light will assist the flowers in pushing up, and help them to expand. The long bulb section, such as *M. Clowesii*, of which there are several varieties; *candida grandiflora*, a most desirable form; and *Regnelli*, with the dark rosy purple variety named *purpurea*, are, on account of their manner of growth, best when grown in pots, well raised above the rim, with plenty of drainage and open soil, as already described. These, too, should be stood in the Cattleya-house, where they will grow very freely, and during early autumn throw up the spikes of bloom which are ever welcome. The rare *M. cuneata*, the lip of which is pure white, will, however, almost always come into flower during January and February. Carefully look through the collection from this time in the matter of watering; as the plants do not dry so quickly, only give water when necessary, otherwise an undue abundance of moisture is very apt to cause rot to attack the young shoots of those that start away in the autumn. *W. Swan, Fallowfield.*

FLOWER GARDEN, ETC.

Most of the bedding-plants have grown and bloomed well this season, but many of the flowers suffered from the heavy rains which prevailed over most parts of the country. From the same cause plants that are so unusually vigorous are consequently in the condition in which frost is most likely to pinch them; this may occur at any time now, but if frost keeps off, the flower-beds and borders may be fresh and enjoyable for several weeks to come. Keep a sharp look-out for decayed flowers, leaves, &c., and have them cleared off as soon as possible. Any plants that are growing beyond their proper limits may require to be thinned out and pinched back to their desired form; wherever they are encroaching on the grass or edging of walks have them trimmed without delay, for sometimes harm may be done before it may be thought necessary to look after it. Get the propagating brought to a close as early as possible. Verbena cuttings are in better condition now than earlier in the season, and will root quickly in a close, humid atmosphere. Climbers that are growing strongly will require attention. The stormy weather has kept the lawns rather untidy. Let them be swept up as often as required, in order to have them enjoyable. The grass still wants the machine frequently run over it, which keeps it firm and smooth. Provision had better be made for securing the *Pelargonium* cuttings in the event of heavy rains or frost setting in; the latter may occur at any time now, as the season is pretty far advanced; and not much to be trusted for tender

things after this time. The best varieties of *Lobelia* should be selected and marked, and the seeds carefully looked for in dry weather. Any other choice seeds may be collected in the same manner. See that the ties are not getting broken which keep *Cupressus*, *Junipers*, and other spiral trees in form; so much rain and wind has been rather trying for them. Have weeds kept under at every favourable opportunity. *T. Blair, Shrubland Park.*

FRUIT HOUSES.

FIGS.—If the same course of treatment as indicated in the preceding Calendar for Figs, viz., August 25, be extended for another fortnight or three weeks beyond the time of clearing the fruit, and conjointly with it a somewhat drier state at the roots be permitted, it will considerably advance the ripening process in the growths of the current year and render them more fruitful for the subsequent one. To accelerate this object, it will also be advisable to withhold water from the roots altogether for the next six or eight weeks. This can be done in the case of ordinary sized borders without any apprehension of danger arising from the borders becoming too arid, providing that hitherto they have had abundant supplies of the element. Attention should also at this season be directed to any requirements in the way of lifting the trees or root-pruning. These are points in management which are occasionally necessary in the cultivation of this gross growing subject: if by reason of too much vigour or from other causes any trees are unfruitful it is a safe plan to either lift the roots partially, or prune them in somewhat hard. This remark applies to these trees generally, but particularly, in this instance, to trees which are to be subjected to forcing operations again ere long, in which case the operation should be performed without much delay, at the same time giving the roots a little fresh compost made up of about half loam and road-sweepings. Keep the growths which are to be retained for bearing fruit next year well exposed to the sun's powerful influence, and any spurs which are not required which impedes its operation should now be removed.

Trees in pots which are intended for early forcing operations should at about this time be overhauled and their requirements attended to. In the case of trees to be shifted into larger pots be careful to have the soil rammed firmly round the old ball, so that in watering this element will penetrate the whole mass of soil evenly. With regard to the trees that do not need to be repotted, they should have the matted roots round the base and the soil removed to the extent of 3 or 4 inches, and, after the drainage is rectified, this space should be refilled with fresh compost. It is usual to employ in this case the same pots again; see, therefore, that the position of the tree in the pot is accurately noted before it is removed, so as when replaced it will occupy its former position. At the same time the surface of the balls should also be dressed down and an equivalent of new compost added. After such matters have been accomplished water the trees, in order to settle down the soil completely. All decayed leaves which fall from the trees should be collected daily, in order to prevent any insect pests which may infest them from being disseminated. *G. T. Miles, Wycombe Abbey.*

ORCHARD-HOUSE.—The most important work in this department includes the potting of early kinds of Peaches and Nectarines from which the fruit has been gathered, and attention to the thorough maturation of the wood of later varieties still under glass. To insure this all late growths will require shortening back to admit of full exposure of the wood to the influence of light, sun, and air, the gradual reduction of the supply of water to the roots, and the maintenance of a dry warm atmosphere by day with abundant ventilation through the night. If red-spider or other insects have gained a footing the trees should be well syringed on fine mornings as the fruit is cleared off, and all strong roots which have found their way through the bottoms of the pots into the border may be checked by the insertion of a sharp instrument to cut off the supply of moisture. Plums, Pears, and Cherries plunged in the open air will be greatly benefited by full or partial exposure of the pots for a time in a position where they can be protected from drenching rains; and if not already done, a shift where necessary into larger pots should be given without further delay. Stop all late growths in Figs, and turn aside the old leaves which interfere with direct action of sun and light on the fruit now ripening. Get in a good supply of stiff turfy loam from an old pasture for potting purposes. Stack in narrow ridges, and protect from snow and rain with thatch or shutters.

If fresh trees are required for potting up, a selection of clean handsome plants which have made firm, moderately strong wood, may now be made for lifting when the leaves are falling. Trees well set with bloom-buds may now be obtained from all the leading nurseries, and these, if carefully potted before the end of October, will give a moderate supply of fruit next

season. Rivers' Nectarine Peach is worthy of extensive cultivation for giving a supply of late fruit. *W. Coleman.*

HARDY FRUIT GARDEN.

Most of the autumn kinds of Apples and Pears are unusually late in ripening, but as strong winds generally prevail about this season and may now be expected at any time, they should not be left on the trees a day longer than is necessary, as a slight shaking will cause them to fall, and fallen fruit is of little or no value except for immediate use, owing to the rapid decay of the bruised parts. It does not require much discrimination to determine when Plums, Peaches, Nectarines, &c., are fit to gather, but as regards Pears and Apples the case is different, and cultivators of these should make themselves well acquainted with the sorts, for without this knowledge they are often plucked too soon, and the result is that they become shrivelled, and never reach that degree of mellowness or finish with the rich melting flesh for which all dessert Pears are so highly prized. Late kinds, such as *Joséphine de Malines*, *Bergamot d'Esperey*, *Glou Morçeau*, and others of that class, should be allowed to hang at least a month later, or till such time as they part readily from the trees by just lifting them up, when if ripe they break off at the joint of the footstalk, and this is one of the best tests as to their fitness to gather. The handling in placing them in the baskets, and from thence to the fruit-room shelves, ought to be done as tenderly and carefully as would be necessary for eggs, and in laying them out there is nothing better than smooth, bare boards to store them on, as straw, hay, or sawdust is sure to impart an unpleasant flavour. Although such Pears as *Williams' Bon Chrétien*, *Louise Bonne*, *Beurré d'Amanlis*, and a few other autumn kinds do not keep long, the season for each may be considerably prolonged by introducing a portion of the forwarder where they can get a little warmth to accelerate ripening, and by placing the remainder in some cool, airy cellar or other situation where the temperature is low, and not liable to fluctuate.

It is to be hoped that nurserymen generally are well-stocked with young trees of Apricots, Peaches, and Nectarines, as the demand is likely to be great to replace those killed or crippled by the unpropitious weather we had during the early part of the season, and it would be well for those requiring such, and who desire to have the pick, to give their orders early, that they may secure what are likely to suit others, as those who come first are generally best served in matters of this kind.

As many may be at a loss which to select it may not be amiss to name a few of the most desirable, and among Nectarines *Lord Napier* is one of the very best, being of large size, highly coloured, and of first-rate flavour. To succeed this *Elruge* and *Violette Hâtive* are next in order of merit, and to follow these *Pitmaston Orange* or *Pine-apple* and *Hardwicke Seedling* are the most satisfactory. The *Victoria* is a first-class Nectarine and the latest of all to ripen, but is not to be depended on unless a warm, favoured situation can be afforded it.

Among the varieties of Peaches the most valuable in point of earliness is *Early Louise*, which ripens at the end of July, and is not deficient in either colour or flavour. *Dr. Hogg* or *Early Alfred* will succeed this, and both are good free-bearing hardy kinds; and to succeed these none are better than *Royal George*, *Noblesse*, *Violette Hâtive*, *Barrington*, and *Walburton Admirable*, the latter of which is equal to *Noblesse*, and the finest and best flavoured late Peach grown. All the above are sure to give satisfaction, and may be relied on as the most suitable to grow either outdoors or in.

The earliest amongst the Apricots are the *Golden Drop* and *Mush-Mush*, the latter of which is rather a shy bearer while the tree is in a young state. *Moor Park*, *Hemskirk*, and *Peach* are the three best of those that ripen later, and are all that are worth growing except for preserving, for which purpose the *Roman* and *Turkey* are most prized on account of being more juicy and of a sub-acid flavour. The trees, too, are hardier and not so liable to canker or go off in the way the *Moor Park* and *Hemskirk* generally do after they attain age or are growing in wet, cold soils or unsuitable situations. The late sunny weather has been very favourable for ripening the wood, but owing to the scarcity of fruit and the abundant rainfall most trees have made a grosser growth than usual, and root-pruning may in such cases be resorted to with considerable benefit. If this is taken in hand at once it will not be without effect next season, for although too late now to induce fruit-buds it will have that tendency in future by causing plenty of fibre and checking any further inclination to over-luxuriance. Filberts are now ripening, and will require close watching to save them from squirrels, which are sure to find them out and carry off the greater portion unless means are taken to prevent them. *J. Sheppard.*

THE
Gardeners' Chronicle.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, Sept. 24 { Sale of Dutch Bulbs at Stevens' Rooms
(and Wednesday)
THURSDAY, Sept. 27—Sale of Orchids, at Stevens' Rooms.
SATURDAY, Sept. 29—Sale of Dutch Bulbs at Stevens' Rooms.

THE details which we are enabled to publish relating to the work done at ROTHAMSTED for the last thirty-five years, constitute a record of the very highest interest and importance. They illustrate very forcibly one striking difference between the procedure in this country and that of others. In Germany, in France, in America, for instance, agricultural stations and physiological laboratories abound—all doing useful work, but all, with few exceptions, maintained by the several Governments or by public means. Rothamsted, on the other hand, is the hereditary property of an English gentleman, the establishment is maintained at his sole cost, and the vast series of experiments there carried out have been devised and fulfilled for purposes of pure science by Mr. LAWES, with the assistance of trained observers and experts, foremost among whom we must mention Dr. GILBERT. By private enterprise, then—by zeal, industry, and talent, which we may well call unrivalled, a long series of experiments have been carried out in magnitude and in importance superior in their way, we may say, to anything that has been done in the experimental farms and laboratories of the Continent.

The bare details given in another column are sufficient to justify this assertion. The general aim of these truly vast series of experiments has been to question Nature as to the best and most efficient means of feeding plants and animals for the benefit of the human race. Although these experiments have throughout been carried out from the point of view of pure science—utility having been a secondary consideration—yet it will be evident to any one who casts his eye over the records now given that direct utility has been served in a greater degree than by any other series of experiments of like character that have hitherto been made. The Rothamsted experiments offer, indeed, another proof that in the promotion and advance of pure science as the primary consideration lies the surest and most certain road to practical utility.

Little need be added by us to the record given in another column. Its bare record of work accomplished is the most impressive commentary that could be made. It will be seen that the experiments were made with a view to elicit from Nature herself in the most practical manner the mode in which the feeding of plants and animals can, under both natural and artificial circumstances, be conducted. To this end the life history of plants and animals has been studied, the nature of their food investigated, the relations between the living organisms and the world around them, the earth, the air, the water, the heat, the light, and their reciprocal interactions, investigated. The mineral theory of LIEBIG has been proved to be erroneous. New and unexpected light has been thrown on the requirements of particular plants. Thus the highly nitrogenous leguminous plants have been conclusively shown not to be specially benefited by nitrogenous manures, and, on the other hand, starch and sugar yielding crops have been proved to be particularly assisted by the application of nitrogenous manures. But we have no space to do more than hint at the general character of the researches made at Rothamsted. The general result is in the highest degree

honourable to Mr. LAWES and his associates, and gratifying to our national self-esteem. These are no mere flower-pot experiments, they may be measured by the acre. These are no temporary or superficial trials, they have extended in most cases considerably over a quarter of a century; and the results have been in every case watched, observed, calculated, and tabulated with as much care as in the more minute proceedings of an analytical chemist. In the field, indeed, the same minute precautions and accuracy of observation and of record have been maintained, so far as the circumstances of the case have permitted, as are expected at the hands of the analytical chemist. Field observations and laboratory work have gone hand-in-hand together, have been carried out with the same method, treated in the same manner, and thus yield a body of observations unsurpassed in extent, in variety, and in accuracy. The results of all this labour and skill have, to a considerable extent, been given in the Journals of the Royal Agricultural and Royal Horticultural Societies and in other publications, but the very number of these scattered records and their prodigious wealth, variety, and complexity of detail render them difficult to be grasped by an ordinary scientific reader. Life is short, art is long. The time seems to us to have come when the directors of this noble experimental station should gather together into one harmonious consecutive treatise the main results of their labour and the legitimate inferences therefrom. We are, of course, aware that to some extent this has already been done. Most of the very numerous publications of Messrs. LAWES and GILBERT contain summaries, but these summaries themselves now require consolidating, and their mutual relationship made clearly evident. One other point remains to be mentioned.

In what other country would services so splendid and so disinterested be allowed to pass unnoticed by the nation? True, such honours as science can give have been bestowed, and agriculturists have not been unmindful of what has been done for them; but surely this is a case for Governmental recognition. Had Messrs. LAWES and GILBERT and their several associates in their respective degrees been soldiers or sailors, they need not have effected a tenth part of what they have done to have been the recipients of State honours and rewards. Doubtless their own satisfaction at the results of their labours is the best and sweetest reward they themselves could look for; but, as a matter of national honour, it is greatly to our discredit that services so long continued and so valuable should have been allowed to pass without State recognition.

Our illustrations represent the Jacobean mansion of Mr. LAWES at Rothamsted (fig. 75, p. 373). Fig. 74 the interior of the laboratory, with its myriads of *pieces justificatives* in the shape of analyses and records. Fig. 73 the rain-gauge, one-thousandth of an acre in area. Figs. 71 and 72 other rain-gauges of like area, but filled with soil of various depths, to show the quantity of rain that percolates through strata of different depths, and others again of smaller area arranged in a circle, and destined to show the amount of rain penetrating through soils of various characters, degrees of consistency, in a natural state or artificially consolidated, and mixed with farmyard and various artificial manures. Further, some of these gauges are intended to show the amount of rain that percolates through a given area and depth of soil when bearing a crop of cereals or other plants with different root and leaf action, &c. The rain so collected, together with the drainage-water from some of the fields, is not only measured but subjected to chemical analysis, to show its constitution. Some of the results of this wholesale plan of investigating the amount and composition of the rain according to different circum-

stances, are indicated in a suggestive manner in the paper at p. 360.

A REMARKABLE old plant of BRUGMANSIA SUAVEOLENS is now an object of considerable interest in one of the conservatories at CASTLE ASHBY, Northampton, the seat of the Marquis of NORTHAMPTON. It really forms a fine tree, for it completely fills the space allotted to it in the house in which it is planted out. The huge head is loaded with its large, pendent, trumpet-shaped, pure white flowers, which are very fragrant. It is quite a matter for conjecture how long this plant has been at Castle Ashby, but Mr. GEORGE BEECH, the gardener, informed us that an old man still on the place remembers it as having been there sixty years ago. Every year it is cut back hard to the old wood, something after the fashion of a pollard, and then at the proper time it bursts forth into growth, and the flowers may be said to be heaped up on the branches at this time of the year. In the same house there is a plant of *Bignonia grandiflora*, which it is believed is as old as the *Brugmansia*. It has a stem of considerable dimensions, suggestive of great age, and during the summer it produces an abundance of remarkably fine clusters of rich orange and scarlet trumpet-shaped flowers. In the same house *Tecoma capensis*, *Plumbago capensis*, *Cassia corymbosa*, trained against a wall, and various parterre flowers are now very attractive, and supply an abundance of bloom for cutting from. In one of the newer conservatories *Sollya heterophylla*, with its charming sky-blue flowers; *Bignonia Cherere*, *Eupatorium glandulosum*, are flowering very freely against a wall; and the old Parsley-leaved *Pelargonium*, *P. apifolium*, with its curious brown and blush flowers, are all of much interest to the visitor. A fine plant of *Desfontainia spinosa* against a pillar is making a fine growth, and its numerous red and orange flowers contrast strongly with its deep green leaves. In one of the stove houses at Castle Ashby Mr. BEECH has covered the wall at the back with various forms of *Hibiscus*, most of which are now in flower. The most striking are *linearis variegata*, with large carmine flowers; *perfectus carminatus*, with very large single red blossoms; *luteo-carpus*, pale salmon-buff; *miniatus semperflorens*, very large red; and *metallicus*, single rosy red. Single flowers of these forms of *Hibiscus*, against a background of fronds of the Maidenhair Fern, are very useful for table decoration, indeed they are fine things to cut from. In the same house *Meyenia erecta* was growing and blooming freely against the back wall. Mr. BEECH has also been very successful in flowering *Tritionia aurea*; a large pot containing six bulbs is now highly attractive, the flowers are large, bold and well coloured. After the plants have gone out of bloom at the end of the summer they are dried off, then the soil shaken from the roots, and the bulbs re-potted in loam, leaf soil and sand, and kept on a shelf in the stove house near the glass. It blooms both in the spring and autumn.

There are still some places remaining about the country where the more elaborate systems of modern FLOWER GARDENING have not altogether stamped out the old-fashioned characteristics of a flower garden. A flower garden at Castle Ashby, complete in itself, is wholly composed of beds of old-fashioned flowers. There are beds of sweet-scented Cloves, Asters, Stocks, Roses, Phlox Drummondii, Salpiglossis, &c., and one of them, a true bed of sweet-scented plants, contained a good selection of scented-leaved *Pelargoniums*, Balm of Gilead, *Aloysia citriodora*, and what is known as the Pine-apple-scented *Salvia*, which well deserves its name for the leaves are richly perfumed with a scent like that of the Pine-apple. Mr. BEECH obtained this from Miss HOPE, Wardie Lodge, Edinburgh, and he grows it in pots in the conservatory for the sake of its delicious fragrance. One of the finest of wall plants is *Ceanothus Gloire de Versailles*. It is a vigorous grower, but while free in growth blooms with great freedom, and it is just now highly attractive, the bunches of flowers being large and striking. A variety of *C. rigidus* with golden foliage is also a very desirable plant for warm walls, and though the yellow variegation is not particularly striking, the plant has always a cheerful appearance at all times of the year. *Pavia californica* is now a conspicuous object in the pleasure grounds at Castle Ashby. The specimens are growing in shady sheltered spots, but they are doing well, and are covered with large panicles of

white fragrant flowers. The foliage is ample and handsome, and in the autumn, when the trees bear fruit, the season of attractiveness is continued up to the fall of the leaf. This Pavia has been well described as "one of the handsomest introductions of recent date."

— In connection with the SLOUGH LITERARY AND SCIENTIFIC INSTITUTION a course of instruction was commenced yesterday, September 21, in the subject of botany, which will be pursued in connection with the Science and Art Department. The course will embrace, besides the chemical preliminaries, the various departments of the science designated as histological, structural, physiological, systematic,

— The Babool, or ACACIA ARABICA, seems to be a much more important tree in some parts of India than it is generally supposed to be. In a recently issued report of the Forest Department of the Bombay Presidency an account is given of the uses of this tree, from which we learn that its wood is preferred before any other for the construction of carts, and every village owns large numbers of these vehicles for the traffic of the country, which is carried on almost entirely by carts. Sugar and oil presses and grain pounders are made of it, and it is used for building the flat-roofed houses of the Deccan. Its branches, covered with long thorns, are invaluable for fencing material; thrown loosely down on the boundary line of a field they come into use at once as protectors to

flowers are more like those of the Orange. As we hope to give a figure of this very interesting fruit in a future issue we defer further notice of the plant at present, merely stating that Mr. GARNIER describes the fruit as superior to any tropical fruit he has ever tasted. It would probably succeed in an orchard-house in this country, and would be a valuable introduction into many of our colonies. We congratulate Mr. BULL as the fortunate introducer of this plant, and Mr. GARNIER on his success in fruiting it.

— Writing on the cultivation of EUCALYPTUS GLOBULUS in Kanara, one of the forest officers says: — "There is one thing that may be said in its favour, and that is, that if found successful, the people would

FIG. 74.—INTERIOR OF THE LABORATORY AT ROTHAMSTED.

economic, and geographical botany. The class will be held every Friday evening from 8.15 to 9.45. The instruction will be by means of class lectures, illustrated by diagrams and the use of the microscope. A constant reference to living specimens will be made, and these botanically described, with a view to impart a useful training in precision of expression, and to facilitate an acquirement of technical language. At the yearly Government examinations all students who are placed in the first class receive Queen's prizes: efforts will also be made to procure the offer of a local prize for the best worked paper in the examination of 1878. Mr. NEWLYN is the teacher, and in view of the admirable training botany well taught affords, as well as from its immediate advantage especially to young gardeners, we wish Mr. NEWLYN a large and appreciative class.

the crops, and are green and effective so long as the crops are on the ground. Its pods provide fodder for sheep and goats. It is prized above all woods for firewood. The gum it exudes is an article of commerce, and is used largely in the concoction of native medicines, cloth-dyeing, and printing. The bark is in request for tanning and dyeing; it is a powerful astringent, and when food is scarce it is eaten pounded and mixed with flour. The roots are also used for tanning, and for the distillation of a native liquor.

— Our thanks are due to Mr. BULL for allowing us to see four fine fruits of the CASIMIROA EDULIS, ripened in the garden of MITCHELL HENRY, Esq., M.P., of Kylemore Castle, Galway. The fruit in question has been called the Mexican Apple. In appearance it resembles an Apple, but the leaves and

everywhere take to planting it about their homes, in consequence of the properties it is said to possess in preventing malaria, and in which such of the natives as have seen it fully believe. In Duarwar, near the market-place, where a few plants of Eucalyptus globulus were planted and enclosed, the perfume given off from them attracted many admirers, and the greatest desire was evinced to touch or take away a leaf or two. One plant, a great beauty, pulled about in this manner, succumbed to the attack thus made upon it."

— Messrs. RUTLEY & SILVERLOCK, of 412, Strand, have sent us a cake of SOAP from China, stated to be made from the seed of the Tea plant, and to be very efficacious when used with water in destroying worms on lawns. The soap in question has somewhat

of the appearance and smell of coarse oilcake. When broken up and mixed with a canful of water, so as to form a rather thick mixture, we found it very efficacious in bringing to the surface and killing a large number of worms from a lawn on cold, wet soil.

— The successful extermination of weeds and creepers in the Indian forests is one of the difficulties the forest officers have to contend with, and one of the most difficult of these weeds to eradicate is the PRICKLY PEAR. This has become quite a pest, and it is satisfactory to learn that the plant is in future likely to become of some use. Its appearance in the Poona districts is, by a local tradition, attributed to a few seeds being brought to Poona from Delhi a century and a half ago. The rapid spread of the plant is due to birds being very fond of the seeds. Till very lately it was thought that the Prickly Pear could yield no return, but it has recently been discovered that the Bahool seed sown in the ashes of the Prickly Pear germinated very quickly, and plants manured with the ash grew vigorously and strong. Further it has been said that this ash is a very valuable soil fertiliser. A series of experiments have been tried by the Deputy Conservator of Forests, Poona, in the use of Prickly Pear as manure, by crushing it and then applying it to the roots of plants and shrubs. The Superintendent of the Botanical Gardens, Gunesk Khind, writing to the Deputy Conservator of Forests, Poona, says:—"Since you drew my attention to Prickly Pear as manure, I have used several hundred cartloads of it. I put it into a tank through which water for irrigation passes; of course it decomposes rapidly, and the water carries away a large portion of the gases that are generated together with small pieces of half-decomposed vegetable tissue. What could be better plant food on a soil from which the vegetable matter has been collected and burned by so many generations?" These favourable opinions on the use of the Prickly Pear, however, are not shared in by all even of forest officers, for one writing on the subject says:—"The superintendent of a botanical garden may employ it as a manure without mischief, but it will be a very disastrous event if ever the cultivators make use of it generally for this purpose. They have no means of crushing it thoroughly, and its use as a manure would inevitably extend the growth of this mischievous plant." This writer also further says:—"I am so convinced of the impossibility of controlling the growth of the Prickly Pear when once introduced, owing to its propagation by birds and animals, that I would prohibit its use as a hedge to forests, or as a substitute for fire-paths." It will be gathered from this, that for the purpose of preventing the spread of fire in forests the Prickly Pear has been recommended, as it grows with such luxuriance, and establishes itself so readily, that impenetrable hedges are quickly formed, and if planted thickly on the outer boundary line of a reserve, it would be practically impossible for fire to penetrate from the outside into the forest. Several species of grass are also recommended as being admirably suited for the same purpose, *Panicum spectabile* being one of the best, and this is stated to grow luxuriantly in the hottest and driest places, shooting vigorously to 3 or four feet in height, with deep roots often a yard long, and 1 inch or 2 inches thick. "It is very sweet and succulent, and always green. A seedling will cover a square foot in one year with deep matted roots. Fire would not travel across it."

— There seems some reason to fear the total extinction of the SCAMMONY PLANT (*Convolvulus Scammonia*) in Turkey. For many years, owing to the wholesale adulteration of Turkish scammony, which includes a large proportion of gum-arabic, flour, and other ingredients, the English drug-houses have preferred buying the root and preparing their own scammony. The following extract from a report by the British Consul at Smyrna will be read with interest, and should be taken some notice of before it is too late:—"The Government," we read, "having allowed the digging of the roots of this drug the crop is annually diminishing, and if the destruction of the plant is not put a stop to the article will totally disappear."

— It may not be out of place just now when we are lamenting the exceeding SCARCITY OF HARDY FRUIT, to remind our readers that the humble VEGETABLE MARROW may be easily converted into a

delicious preserve such as may well be acceptable in any family circle. The mode of its preparation was explained in these pages about this time last year, and shows that with the addition of such simple flavouring materials as sliced lemon peel and ground ginger, the flesh of the Marrow may be converted into a most pleasant luxury. The Vegetable Marrow is so easily cultivated that it may well form a staple product in every garden. It is also comparatively independent of seasons, as it is rare indeed that the crop is a failure. In this respect, although tender in constitution, yet it may well be classed as a most valuable and reliable hardy fruit.

— *NELUMBium ASPERICAULE* is flowering in the Lily-house at Kew. It is a great improvement on *N. speciosum* for garden culture, requiring a lower temperature, blooming more profusely, and having flowers that are even more magnificent. The petals are broader than those of *N. speciosum*, narrowing less to the base, with deeper rose colour over the entire surface. The glow of colour within the flower is, to the eyes, almost like that of some molten metal. It was raised, we believe, by the late Mr. SYLVESTER. The above specimen is growing in a pot, which seems quite sufficient for its development.

— We understand that it has been decided to hold the next spring exhibition of the Royal Caledonian Horticultural Society in the new Vegetable Market, Edinburgh. For light, space, &c., there cannot be a better situation for a flower show.

— The RAINFALL which has characterised the past summer, especially in the North, has not been confined to "our tight little island." A private soldier, serving with the United States' troops now engaged in holding the Indians in check in the remote portions of Nebraska State, mentions in a letter to his friends here, dated August 21, that "the Indians have endeavoured to fire the woods repeatedly, and so burn out the camp, but owing to its having been such a wet season everything is too green to burn." In spite of this EXCESS OF MOISTURE, however, it is unpleasantly dry at times, as he further mentions his belief that "it is the worst country in the world for dust, as when the wind blows the air looks like a London fog in November, and no one will face it; and as to going against it, not even a mule could do it." At the date of the letter it was "already beginning to grow cold, and one finds it comfortable to stay near the stove, for the country is not blessed with a very long summer; but when it comes it comes with a vengeance, and thus makes up for its short stay. Last month it was as hot as I have found it when under the equator." Further on he makes a singular reference to the healthy character of the climate, as in advising his friends to have no fear for his health, he says:—"I am in the very best of health and spirits. This is a very healthy country, and a consumptive person is quite unknown here. There is a common saying that people never die here—they are gradually withered up, and finally blown away. A visit to the graveyard will support this opinion, inasmuch as it is found that few that lie there have died, but must have been murdered." This excessive prevalence of cold steel probably accounts for the health-giving qualities of the atmosphere. If, however, the denizens of that State would but be content to take it in smaller doses, perchance they might all live to be blown away in the end.

— We learn from the *Revue Horticole* of the decease of Count LEONCE DE LAMBERTY, one of the best known and most respected of French horticulturists.

— Mr. R. GILBERT requests us to state that he intends showing at the Royal Horticultural Society's Fruit Committee, on Tuesday, October 3, what he terms the true Gros Colman Grape, and he will esteem it a favour if Grape growers will send a bunch of that variety for comparison. Mr. GILBERT also intends exhibiting another seedling Melon.

— It would seem to lovers of hardy border plants almost impossible to write in terms too generous of the singular beauties of the varieties of the ANEMONE JAPONICA. We have in these probably the finest and most effective of hardy autumnal border flowers adapted to any soil, and when once planted simply requiring to be let alone. The original form of *Anemone japonica*, good and pleasing as it is, is

greatly excelled in size of flower, height, and robustness of growth by its compeers, *japonica alba* and *japonica intermedia*, the latter a pink-shaded form of *alba*. We recently saw established plants of these, from 4 to 5 feet in height, and covered with hundreds of flower-buds; these must, ere now, have been truly grand specimens. This *Anemone* does remarkably well in pots, and it will be a strong recommendation to many persons in its favour that it seems to have been specially designed to gratify the modern passion for cut flowers.

— We hear that the Hereford fungus meeting will be well attended this year, and that, amongst other visitors, MAX CORNU, of Paris, will be present.

— The number of the *Hungarian Journal of Botany* for this month—*Magyar Növénytanilagok*—pays this country the compliment of publishing a biographical sketch of Dr. STEPHEN HALES, the vegetable physiologist, who was born on September 17, 1677. In the same issue a reprint of the portrait of our distinguished countryman, which appeared in our columns on January 6, 1877, is given. How many of our physiologists, we wonder, would have remembered the bi-centenary of HALES' birth. The institution, however, of the physiological laboratory at Kew may be taken as an augury that the study of vegetable physiology will not be neglected in the future as it has been in the past, from the time of HALES to our own day, with some exceptions.

— M. CARRIÈRE records, in a recent number of the *Revue Horticole*, an instance of monœcism in *Cephalotaxus Fortunei*.

— The TELEPHONE has already been made of practical utility in a deep mine in Cornwall, where it has been found serviceable in communicating from the surface to the interior of the mine. We may look forward to this electrical speaking-tube being made use of to communicate orders from the gardener's cottage to workmen at a distance. In fact, the practical utility of the invention is so apparent, that a very short time will ensue before the instrument becomes general.

— A curious instance of bud variation is figured by M. CARRIÈRE in a recent number of the *Revue Horticole*, in the shape of a branch of *PLATANUS ACERIFOLIA* producing leaves of a different form from those of the ordinary Plane. The leaves on the sport are, in fact, nearly entire, and a little raised at the margins so as to present a hooded appearance.

— The losses among leading botanists have been very great of late. France has lost BRONGNIART and WEDDELL, Germany laments BRAUN, and now Italy has to bear the loss of her foremost and best-known botanist, PHILIP PARLATORE, the Director of the Royal Museum of Natural History and Physics at Florence, and Professor of Botany. Professor PARLATORE was born at Palermo, and died on the 9th inst., in his sixty-first year. In this country he is best known for his "Monograph on Conifers" in DE CANDOLLE'S *Prodromus*, and for his unfinished *Flora Italiana*. These works, and the splendid and well-ordered museum and herbarium at Florence, will form his best monument. Professor PARLATORE was the president of the Royal Tuscan Horticultural Society, and of the committee for the Botanical Congress which met in Florence in 1874, but his ill-health prevented him from taking any active part in the actual business of the meeting, to the great regret of the botanists assembled from all parts of the world. Professor PARLATORE had numerous friends in this country, by whom he will be regretted as much for his personal qualities as for his scientific attainments.

— The *Journal des Roses* gives an account of the Rose show at St. James' Hall in July last, which makes us wish that popular names of places, as well as of plants, could be abandoned in favour of appellations that could be made familiar to the educated reader of all nations. Where, for instance, is "Moulton Hyld, Chonnauck"? Can it be the forest where a certain "wyld savage" is supposed to roam?

— Some correspondence lately took place with reference to the "wild Lily," stated to grow in a gravel path. The upshot was that some correspondents obligingly told us that the plant intended was

the common Bind-weed, *CONVOLVULUS ARVENSIS*. We see our American friends call it a "vine," the word vine being used in a very wide sense across the Atlantic. These instances ought to convince grumblers of the inconvenience of popular nomenclature; hard words are bad, but they are better than appellations which are not only vague but altogether misleading. Some people have vague notions on natural history matters: a lady the other day in our hearing declared the sea anemones in the Eighton Aquarium to be "something between Mushrooms and flowers."

— We have before us the first part of the *Journal of the British Dairy Farmers' Association for the Improvement of the Dairy Husbandry of Great Britain*. The part opens with a simply written but most useful article on cheese-making, by Dr. VOELCKER, and various other articles and reports follow, all calculated in their degree to remove the imputation that in all parts of the country "the dairying of the district consists simply of spoiling good milk, cheese and butter being made that would not pay for the cost of the production of the raw material, milk." Those who know what London butter and London milk are will welcome the foundation of the Dairy Farmers' Association, and of their journal, which is well printed, well edited, and sufficiently illustrated.

— Eucalyptus culture in the Isle of Bourbon seems to succeed and prove beneficial in rendering the climate healthier. In the temperate zone especially, at an altitude of between about 1500 and 3000 feet, large plantations already exist. A writer in the *Bulletin de la Société d'Acclimatation* mentions one of several acres in extent which had the appearance of a real forest. He says, "I regard the introduction of these trees as most serviceable. The marsh fevers which desolate the island have not been able to pass the belt of Gum trees which surround my estate; not a single member of my family or work-people has been attacked by fever." The writer, a Mr. CHATEAUVIEUX, who was elected President of the Chamber of Agriculture of the colony in 1863, commenced operations about that date, and he has already felled trees which have furnished good planks 13 feet long. In what he calls the glacial zone—that is, above an altitude of about 3500 feet, where the mean winter minima are 20°.75, and the mean winter maxima are 54°.5—*E. globulus* grows slowly, but is less easily uprooted by hurricanes. At an altitude of 4000 there are large flourishing plantations, as mentioned above. At 1600 feet the Red Gum grows to a height of 65 feet in six years, but it does not succeed in the cold region. These little items of information are interesting and useful.

— The third annual Conference of the CRYPTO-GAMIC SOCIETY OF SCOTLAND has been postponed until October 17, 18, and 19, instead of October 10, 11, and 12, as previously announced.

— The annual cost of keeping in order the TREES, SHRUBBERIES, and SEATS upon the boulevards and in the public squares and gardens of PARIS is nearly 2,000,000 fr. It is estimated, says the *Builder*, that the trees in the avenues and boulevards of Paris number 82,201; those in the cemeteries, 10,400; and those in the squares and courtyards of various buildings, 8300. There are also 8000 seats for the accommodation of the public. The expense of keeping up all the extra-mural recreation grounds, exclusive of the Bois de Boulogne and the Bois de Vincennes, is rather more than 300,000 fr.

— The West of England still holds its own in the matter of FUCHSIA GROWING, and at the Bath floral *fête* on Wednesday, the 8th inst., Mr. J. LYE, gr. to the Hon. Mrs. HAY, Clyffe Hall, Market Lavington, was placed 1st, with nine plants of such merit that, though Fuchsias are invariably shown fine at Bath, these particular plants were considered some of the finest ever seen. The specimens were of medium size, graceful in contour, and superbly flowered. On this occasion the 1st prize for nine Fuchsias at Bath was a handsome silver cup, and Mr. LYE has crowned his previous efforts by winning it. He has this year taken eight 1st and two 2d prizes; and the latter were awarded him at Trowbridge, where he is generally invincible, as his large plants were not then in perfect condition, and he had to stage some smaller in size than usual. Why is it that while Fuchsias are generally so well grown in Wiltshire and Somersetshire,

they are so indifferently grown elsewhere? There is scarcely another plant that repays good cultivation as the Fuchsia does, and when well done it is one of the most attractive features in an exhibition tent. And yet they are often a poor display, not at all up to the average of many other flowering plants.

— A novel way of clearing a CORNFIELD of INSECT PESTS is reported from Budiansk, Russia. It seems that the last harvest was a very unequal one, the produce of one farm being abundant, and of the next one almost *nil*. This was in great measure owing, it is said, to the ravages of "a species of black beetle." To remove these insects from the ears of Wheat some farmers adopted the plan of dragging a piece of rope held by two men over the plants, and this had to be frequently repeated. This plan must certainly be an expensive one, inasmuch as it does not exterminate the insects but simply removes them for a time. There is something comical in playing with insect pests in this manner.

— We have been favoured with an inspection of a drawing of the fruit of HOYA CARNOSA which was produced in a garden at Wimbledon. Only a single follicle was ripened, and this of the elongated form so common in this order. The seeds, too, have the usual hairy appendage. The construction of the flower is such as to necessitate insect agency, but what the particular insect may have been in this case we cannot say.

— The French Vice-Consul at Larnaca, Isle of Cyprus, M. DUBREUIL, in a communication to the President of the French Society for Promoting the Acclimatization of Useful and Ornamental Plants and Animals, respecting the vineyards, or rather Vines—for they are left pretty much to themselves—gives some account of a DISEASE which formerly attacked the VINES there, but which has since disappeared. During seven years, from 1859 to 1866, it is stated the Vines were stricken with a disease characterised by a kind of ash, covering the berry at the time when they ought to be ripe. No one attempted to find a remedy for it, though the ravages it committed were so serious that some of the Vine growers decided to root up their Vines. However, the disease seems to have died out, for no traces of it have been observed since 1866. What it really was nobody seems to know, but it is suggested that its exhaustion or extirpation might be due to the presence of the Sumach in the vineyards. After the outbreak of the disease the naturally indolent islanders took little care of their vineyards, allowing the shrub named to completely overrun them; and since it has spread so much the disease has not been seen. The total disappearance of the disease, whatever it may have been, is highly gratifying; but that the Rhus expelled it is exceedingly doubtful. It would be good news, indeed, if we could be sure that the Phylloxera was becoming less prolific and diminishing instead of extending its area of depredations. The same writer, referring to a report of an Oak growing in the same island, and bearing acorns as large as one's fist, states that as regards their actual size it has been considerably exaggerated. They are, however, very handsome, and three times as large as those of our largest Oaks.

Foreign Correspondence.

THE VALENCIA ORANGE GROVES.—Between the Orange groves and the sea for a width of several miles, there is a forest of Olive and Carouba trees from 20 to 30 feet high. They evidently serve to break the sea winds, and to protect the Orange trees from their contact. These Orange groves occupy the triangular plain above described, the two sides of which north-west and south-west are formed by sheltering mountains, whilst the base is protected from the easterly sea winds by the wide belt of Olive and Carouba trees. These protecting trees not being high the Orange trees are cultivated as bushes. The central stem is cut about 1 foot, or even less from the ground, and three, four, or five branches are carried up as a bush, and not allowed to grow above 10 or 12 feet high. To this mode of cultivation there is no exception whatever. Tens of thousands of these large Orange bushes are seen, but not one large regular Orange tree such as are found in Majorca, Sardinia, Sicily, and the Riviera. In the valley or vega of Valencia, above the city, the same system of cultivation is exclusively followed, as I found in a previous journey. Thus once more is the necessity of protection from wind exemplified in the cultivation of the Orange tree. In Majorca it is ex-

clusively cultivated in a large crater-like valley; in Minorca it is only seen in a deep serpentine valley, formed by a fault in limestone rocks; and here on the east coast of Spain we find it cultivated like a low Apple bush, in order to ensure the necessary protection from wind. In all these countries and regions I have always found Orange trees growing in calcareous soils.

The trees seemed perfectly healthy—to have escaped so far from the terrible *secco*. I could not discover whether they had been grafted or not. The crop of Oranges had been so thoroughly gathered and disposed of that at the small town of Castellon, where I passed the night, we could not procure one for love or money. Castellon, the capital of the fertile Orange covered delta plain, was formerly a fortified town of some local importance, but appears now to be merely an agricultural centre. The accommodation is essentially Spanish, that is, the *fonda* or inn leaves much to be desired. I would, however, say that in Spain the habit of using exclusively iron bedsteads and a small amount of bed furniture, the absence of carpets, and the paucity of furniture generally, with the universal whitewashing of the walls, secure the travellers and inhabitants greatly from vermin. Then, although the meat is tough, naturally very indifferent, it is so long stewed that it becomes tender and eatable at last. I myself have always managed to live and flourish when travelling in Spain, finding therein "the elements of nutrition" even if not presented in the French or English style. The wine and bread are always good, which is not a bad foundation for a meal.

Pursuing our course the next day, northwards, a few miles from the shore, we left the irrigated delta and passed through an unirrigated, therefore arid region. Here we found the scrub Palm of Algeria, the *Chamerops humilis*, growing wild, freely, and abundantly, evidently a native of the soil. I had seen it previously in the south of Spain, in Murcia, and Andalusia, growing wild as a scrub plant under the same circumstances. This *Chamerops* may be said to belong to Europe, as well as to Africa. It was formerly a common plant in Provence and the South of France generally, although now quite extirpated, and only growing in gardens. Along with the *Chamerops* were numerous Aloes, the *Lentiscus*, and the prickly Broom of the South of Europe. The mountains in the background were very naked and arid, quite burnt up and denuded. There were water-courses, but no water or water plants; river beds, but not a drop of water in them. Every now and then we came to small towns or villages, very poverty-stricken, located evidently in places where some little water could be obtained by wells. Around them were fields of Wheat and Barley, very clean, Vines, and Mulberry, Fig, and Walnut trees. The wells were mostly worked by rope and pulley, sometimes by mules.

We were passing through a part of Spain that had been occupied and ravaged by the Carlists during the war, of which we were rather uncomfortably reminded. As the train slackened at each station there was a soldier with gun in hand on each side of the line, and on reaching the platform we usually found two or three more awaiting our arrival. On inquiry we were told that these troopers were there to secure the safety of the passengers. It appears that after the Carlist bands ceased stopping the trains themselves, as they were wont, some of the gentry who composed them set to work on their own account in the following way:—They used, singly or by twos, and well-dressed, to get into first or second-class carriages, and once the train was in motion to draw out revolvers and take all the money and jewellery of the passengers. On the train slackening, at the next station, they opened the door, got out, and ran away. The soldiers had orders to shoot all who did so, and we were cautioned never to get out before the train stopped thoroughly, for fear of a mistake—a caution we took care to obey.

Emerging from this sunburnt, waterless, arid district, we suddenly came upon a fertile irrigated valley, in the midst of which was a broad yellow river, the Ebro, coming down from the glaciers of the Pyrenees, and making the land on each side laugh with wine, corn, oil, fruit, nuts, and Walnuts, for we had reached the southern limit of the Barcelona Nut region. There was a good-sized town on its banks, Tortosa. After leaving the smiling valley of the Ebro we once more emerged on a barren, waterless region, with bleak, sunburnt rocks, watercourses without water, and a scrub vegetation, principally *Chamerops Palm* and

Lentiscus; I think I may add Gorse, with here and there patches of miserable, half-starved cereals, Vines, and Olives, doing their best to live. We reached Tarragona, an old town formerly of great political importance, with a good port, the commercial outlet of the large and rich valley of the Ebro. At Tarragona I was principally struck by the number of new houses and streets, the former tall and built in the French style, one most unsuitable to a warm climate, and by the destruction of the fortifications which was being actively carried on. The massive thick walls were being pulled down, and the deep moat filled with the stones and rubbish of which they are composed. No doubt such destruction is progress, but it makes the traveller muse to find it going on everywhere on the Continent. Thus the olden times are passing away from us, and light and air are being let in physically as well as morally.

The next day we took the railroad that runs along the southern slopes of the Pyrenees to join the one from Madrid to Bayonne, and made a leisurely progress, sleeping at Lerida, Saragossa, and other towns on the road, so as to be able to study the country, its productions, and its people. I found the same agricultural and social conditions as in the central regions of Spain, Aragon, and Castille. The country is one rolling plain, presenting every variety and form of geological denudations, all but without trees, and principally cultivated with poor cereals on the fallow system.

The Spanish peasants think that birds eat the corn, and that trees harbour birds, so they cut down the trees, and the country presents the character of endless, melancholy, treeless plains with a poor stunted cereal vegetation. Then, owing, no doubt, in part to the lawless condition of the country the agricultural labourers live in the towns, not in farms or villages, so that these plains seem lifeless, unpopulated. The passing traveller wonders who does the agricultural work he sees carried out. Thus I was told at Saragossa that out of a population of 70,000 more than 40,000 were agricultural labourers, who tilled the land for 10 or 15 miles round. They were miserably clad, appeared miserably fed, and were evidently spending a mere animal existence, whilst observing rigidly all the outer forms of their religion. In every one of these wretched towns there was a magnificent cathedral. Some, such as the one at Saragossa, are undescribably beautiful, thrilling, awe-inspiring. These towns give the traveller the key to the social condition of the middle ages, still perpetuated, partially at least, in these out-of-the-way regions of Europe. At the entrance of the town the frowning feudal castle, around the town the massive walls and deep moat, in the centre the magnificent cathedral. Between the two the peasantry and citizens, like Olives between two millstones in an Olive mill, crushed between the two, absorbed between the two. It must have taken centuries of their labour to construct the double monuments, the castle and walls, the sumptuous, grand cathedral. To these poor souls the cathedral, with its sombre grandeur, its incense, its chants, its music must have always appeared a foretaste, an ante-chamber of heaven itself. The cathedral at Saragossa even had that effect upon me, the travelled, argumentative Anglo-Saxon.

For a hundred miles or more we followed the valley of the Ebro, always seeing the same facts reproduced; with irrigation fertility, without its sterility—all but barrenness. When along with water there was protection from the North, and the barometer showed that we were only some 500 feet above the sea, Olive trees appeared, and Vines became more numerous. We were constantly in sight of the Pyrenees sloping down to the south, with the higher summits still covered with snow (May 23), from whence came down wind still cold.

The vestiges of the late civil war were more decided than on the coast. In addition to the troopers at the stations we had before our eyes the evidence of past combats in the ruins of the stations. They had all been battered and destroyed by fire, and the station work was being done under sheds. Each station it appears had been a battle field, taken and retaken a dozen times.

As we approached the Atlantic the climate evidently changed, became less dry and scorching, moister. Trees, grass, pasturage appeared, a more careful system of agriculture, and numerous villages. We were entering into the Basque provinces, which are fertile, well cultivated, and populous. *J. Henry Bennett, M.D., The Ferns, Weybridge.*

INFLUENCE OF TREES AND PLANTATIONS ON SOIL AND CLIMATE.—One of the greatest and most important objects to be aimed at in the improvement of property is to produce shelter, for all animals (not even excepting poultry) are fond of warmth and shelter, and do not thrive well without it; and as our severest weather comes from the north and east these points should be best guarded and protected. In some cases summer as much as winter shelter is required, as in the case of stud farms; when the horses are housed in winter, and only remain out in summer, and when a cold and stormy day occurs, as is common in our variable climate, they suffer much without proper shelter. Upon many upland and Highland farms the stock cannot remain out during winter, but have to seek winter shelter in more congenial places. When a wintering is sought for, it is valued more for its dry soil and shelter than for the herbage upon it, and nothing pleases the shepherd better than an old plantation where the stems of the trees are all cleared of their dead and scraggy branches.

As the first and greatest of all improvements of land consists in drying it, draining is obviously the first thing to do, and may be done in various ways to suit the requirements of the case. Underground tile drainage is the best, both for arable land, pasture ground, and also plantation. But for the latter purpose the underground drains are objectionable on account of the roots entering and choking them, and for that reason open surface drains are often preferable, at least in extensive operations. Trees have a very absorbing and drying influence upon the ground, so much so, that when a piece of ground is planted that is termed wettish, in a very few years it becomes perfectly dry. This is eminently the case with soft mossy ground suitable for the growth of Norway Spruce, which is the best kind of tree to plant for the purpose of drying the ground, but has few other recommendations. While trees dry the ground very effectively when once they start growing freely, there is at first a difficulty in getting them to start growth, in consequence of the low temperature of the soil; hence the frequent, if not general necessity for draining the surface, with shallow drains, before planting. The drying influence of trees is so slow and imperceptible that by many it passes unobserved, and they only come to see the amount of water that has either been absorbed by the trees and evaporated, or through the shaking of their roots when the plantation is suddenly cut down. In cutting down a plantation two important results are produced, namely, the excessive heating of the soil in hot weather—I mean heating it beyond the temperature it attained while covered with wood, and soaking with water in the winter time in rainy weather. In confirmation of this view the late Lord Lovat, Beaufort Castle, told the writer that on one of his estates he used to creep while deer-stalking upon his hands and knees, through an extensive plantation quite dry and comfortable, and the first time he required to go over the same ground after the wood was cut down he would have required fishing boots, it being completely covered with water in many places, and all the ground very much wetter than he had ever seen it before. Now if cutting down a plantation so greatly increases its wetness in winter and dryness in summer it is evident that plantations keep the soil more uniformly dry, warm, and comfortable at all seasons than it would be without them.

Another benefit arising from the planting is that of raising the temperature. Drying the soil is only another term for heating it, but I think there are other ways by which trees raise the temperature besides merely drying the ground. I have noticed that snow melts sooner in a plantation than outside of it, and if a certain quantity of snow is laid near the base of an old tree it will melt sooner than the same quantity will at a distance from it or in the open field. The duramen, or heart-wood, of trees does not freeze. In cutting down old trees in frosty weather the heart-wood is as soft as at midsummer, but it is otherwise with the sap-wood, which becomes so hard at times as to resist the saw or axe. A dead tree is also warmer than a live one, until the former becomes soaked with water, when it becomes colder than the latter. Any one blindfolded can tell from the touch which is the dead and which is the live

tree, and those who have studied the subject well can in like manner say from the touch which is the old and which is the young tree, assuming both to be healthy and growing.

A still further benefit from trees is that of opening the soil through the leverage of the stem over the roots during a breeze of wind. The upheaving of the soil amongst the roots is very considerable, and when the earth is thus opened and loosened heat and air are thereby admitted, to the great benefit of the trees and the heating of the ground.

Another advantage of planting is the strengthening of springs, probably not all, but many of them. I know of at least two springs which have greatly increased in volume as the plantations surrounding them have grown up, and both went dry soon after the plantations were cut down. The shading of the ground by means of the branches and leaves prevents it from ever becoming unduly heated in summer, or cooled in winter. The soil amongst trees is drier and warmer than in the open field, but, at the same time, the grass in a plantation after dew or rain is wet for hours after it is dry outside the fence. Whether plantations do most good or harm to grain crops as such is a subject of dispute. They help to increase sparrows, and other small birds which devour grain; they also encourage rabbits, which injure it. In late and wet seasons they prevent it from being harvested, and in some cases from ripening; they prevent frost from leaving the ground on the north side of the plantation. The roots of the trees extend far and wide, rob the soil and choke drains. These and other complaints may be truly lodged against plantations, but, on the other hand, there is much ground that was not worth 1s. 6d. per acre that is now letting at five times that amount, and at the same time bringing to perfection a crop of trees worth more than the ground they occupy. As various other important advantages arise from trees and plantations too numerous to denote at present, they must be left in abeyance and resumed in my next paper. *C. Y. Michie, Cullen House, Cullen, N.B., September 8.*

Home Correspondence.

The Fruit Crops.—There are, I believe, more Apples in this neighbourhood than there was at one time thought to be; but the fruit is in general small. Some kinds have very heavy crops, whilst others have little or no fruit; even the same kinds have not crops alike in the same garden or orchard. One tree happens to be heavily laden, whilst another of the same kind growing close by has no fruit. Some trees here are heavily laden, others have partial crops, whilst some have no fruit. The following are the sorts of Apples bearing fruit here:—Four trees of Cockpit have an abundant crop; one Cockpit, light crop; one Improved Cockpit, an abundant crop; one Improved Cockpit, moderate crop; one Keswick Codlin, a good crop; one Keswick, very light; two Dumelow's Seedling, light crop; two Yellow Ingestre, good crops; one London Pippin, a good crop; one Lamb Abbey Pearmain, a good crop; one Claygate Pearmain, a moderate crop; one Yorkshire Greening, moderate crop, fruit small and some deformed; two Wormsley Pippin, moderate crop; two Hawthornden, heavy crops; one Sykehouse Russet, a good crop; one Old Nonpareil, moderate; one Manks' Codlin, moderate; one King of the Pippins, abundant; one Sir Walter Blackett's Favourite, good; one Ribston Pippin, a few fruit; two Warner's Pippin, moderate; two Court Pendu-Plat, moderate; two, of a kind I do not know, good; also one tree each of two sorts I do not know, good crops. There are several trees with a few fruit and some with scarcely any. The nearest tree to the Keswick Codlin that has a good crop, is another Keswick that has no fruit; then at no very great distance from the King of the Pippins tree that has an abundant crop, is another of the same kind that has very few fruit. There can be no question as to the injurious effects of the severe weather of the past spring on fruit trees whilst in bud and blossom, but the severe weather, in my opinion, was not the sole cause of the great failure of the fruit crops. I believe the great fall of rain in September and October last year also contributed to the failure of the crops—the wood and buds never got properly perfected and matured, and when the buds expanded in spring, being weak, they succumbed to the long continuance of severe weather. The Keswick Codlin and King of the Pippins that have crops this season had, if I remember rightly, very few fruit last year, whilst the Keswick Codlin and King of the Pippins that have little fruit this year had good crops last year. Several of the trees that have crops this season had very few fruit last year. The Cockpit is a well-known and a favourite Apple in Yorkshire. The tree

is of a stiff, sturdy habit of growth, forms strong, close spurs, and is a most abundant and a very certain bearer. It is only a small Apple. The sort that I know by the name of Improved Cockpit is a much larger and flatter Apple than the Cockpit. The tree is of a vigorous habit of growth, and a great bearer, but the fruit does not keep very long. With me they generally decay rapidly in December, whilst the Cockpit keeps until January and sometimes through February. Pears are a lighter crop here than they have been for some years. On the standards there are only a few Beurré Diel, Beurré Bosc, and Louise Bonne of Jersey. The pyramids are a great failure, only a few fruit on a Ne Plus Meuris, Bergamot d'Esperen, and one or two other sorts. Even on the wall trees this year the crops are very light. The following are the best here:—Two Easter Beurré, a good crop; two Beurré Rance, a fair crop; two Glou Morceau, moderate; one Winter Nelis, moderate; one Beurré Diel, fair crop; one Vicar of Winkfield, moderate; one Hacon's Incomparable, moderate. There are a few fruit on some of the other trees. On

stem. *M. Leichtlin*. [Mr. Fitch sends us a tracing from his original drawing of the plant at Kew, which certainly does not indicate the habit described by M. Max Leichtlin; moreover, the specimen from which the drawing was taken has been preserved, and this, Mr. Fitch tells us, shows leaves commencing a few inches from the ground, gradually decreasing in size upwards till they pass into bracts. The flowers produced were about 5 inches long, but native specimens show a spike with eight flowers, each $6\frac{1}{2}$ inches long. Eds.]

Strawberries.—In your excellent Fruit Supplement last week, after mentioning several varieties of Strawberry as good for growing, "Z." says if only one sort can be grown he would recommend that this should be the Viscomtesse Héricart de Thury. Allow me to give my experience of this year. Out of over 250 plants I did not get 2 quarts of fruit from the Viscomtesse, although there was a profusion of bloom—the spring frosts have cut them off; while from the Stirling Castle Pine, which is by some considered

quainted with. It certainly would make a noble plant for massing in beds, singular in form and attractive in colour; a single plant will cover more space than a dozen Echeverias, equally handsome and far from being so commonplace; it is of the easiest possible culture, hardy and evergreen, or persistent in its foliage. Those who indulge in making carpets with plants should look out for this. *Thomas Williams, Ormskirk.*

Autumn-flowering Iris.—Accompanying I send you a plant of *Iris ruthenica*, with a flower on it, which has been blooming for some time freely at my grounds at Tooting; at the same time last year it flowered in the same position. Paxton gives it as flowering in May, but it is evident that in this country its time of flowering is in September. It is a remarkably distinctive plant, forming a circle of fan-shaped foliage, and from the heel of each fan come one, two, or three flowers. We have had this plant in our possession for many years, but only succeeded in flowering it last year and the present, having

FIG. 75.—THE MANOR HOUSE, ROTHAMSTED.

Marie Louise, of which there are here several very fine healthy trees, there are very few fruit. Apricots have not been so scarce in this neighbourhood for some years. Peaches are also scarce here; there are three trees that have a moderate crop—one Walhurton Admirable (or what I have as that sort), the other two sorts I do not know. Plums, with the exception of Victoria, are very scarce; here there are several trees of Green Gage, and I cannot see a single fruit on any of them. The present and last year have been very bad ones for fruit growers in this neighbourhood. Labour is dear, the crops have been light, and the importations from the Continent have been great. The immense quantities of foreign fruit that come into the market keep down the price of home-grown, to the benefit of the consumer but to the detriment of the grower. *M. Saul, Stourton, Yorkshire.*

Lilium cordifolium.—Allow me to say that your artist has made a mistake in the portrait of *L. cordifolium*; unlike *L. giganteum*, the stalk is not leafy, but rises bare to the height of 1 to 2 feet, and then six to eight leaves appear in a sort of rosette. This is one of the principal features in its distinction from *L. giganteum*, which is clothed regularly all along the

identical, I got over a quart to the root. But Sir Charles Napier was my best cropper. After many years of trial of a number of varieties, I should say that either of the two last, the former for choice, were the best when only one sort could be grown; they are good in flavour and colour, and abundant bearers. So is the Viscomtesse, but so early that the late spring frosts spoil it. *Harrison Weir, Weirleigh, Breuchley.*

Euphorbia Myrsinites.—Perhaps no race or tribe of plants are more diversified in form and habit than the Euphorbias. Many of them are so singular and grotesque that they appear to connect themselves with the vegetation of the coal period. They assume every possible shape and size, from the tree to the small annual. Many of the herbaceous forms are very handsome, and our native *E. Paralias* is no despicable plant, but certainly the most handsome of the herbaceous kinds is *E. Myrsinites*. I scarce know of a handsomer hardy plant than this: it throws up a number of stems about 1 foot long, densely clothed with bold, almost imbricated foliage, so decidedly glaucous as to be almost blue—the stem, close to the ground, giving the plant a strange, yet very handsome appearance, unlike any other plant I am ac-

changed the situation and the class of soil. At the present time it is growing in a bed between two lines of Poplars, and in a dampish part of the grounds. I send you at the same time some flowers of *Iris pumila*, which has been blooming tolerably freely for some time past with me. You will see from the specimens sent—some being over, others open, and others in bud—that the succession of bloom is likely to be continued for some time yet. *P. Barr.*

Flow of the Sap.—Seeing an article on this subject, I thought my experience bearing upon the same subject might be worth giving. About ten years since, I planted many young fruit trees, two of which (*Blenheim Pippin Apple*) grew more freely than all the others, but neither of these two had any blossom from year to year. I was advised to root-prune them, and gave orders to a new gardener to do this. To my great annoyance he took upon himself to ring them, by cutting out the bark, about an inch wide, entirely round the collar of the stem, about 2 inches below the branches. I told him he had killed the trees. He was very indignant, and said he had done many so in his time, with great success. The next spring nearly every bud on the tree was a bloom, scarcely a leaf

worth the name making its appearance; all the bloom dropped off without setting a single Apple. The next year there was a similar result, but very much more feeble, and the following year both the trees were quite dead. During this time the bark below the ring appeared to dry up, and became very thin, while that above the ring became much thicker, which appeared to me very extraordinary, and altogether to suggest many points worthy of study to those who are interested in the subject. *C. A.*

Fruit of the Wild Rose.—The French have a mode of preparing the fruit of the Dog Rose as a confection for dessert and as a table sauce, but it requires a great deal of attention in consequence of the bristly hairs which line the interior of the hep. The hair and seeds have to be removed, and then the pulp has to be steeped in warm water or a little white wine for three days, until it is quite softened, when it requires bruising in a marble mortar with a wooden pestle and straining through very fine muslin or a close hair sieve. The sweetish, acidulous taste found in the pulp is said to depend on citric and malic acids. *H. E. Watney.*

The Potato Disease.—I have seen Mr. Worthington Smith's instructive illustrated contributions on the above subject. Beach Cottage having a seaside garden the care of the Potato plot there has enabled me to verify his painstaking researches. Thanks to the light of his revelation, the true nature of the disease is now discovered, but a remedy is one of the pressing wants of the time. Thinking often over Mr. Smith's investigations, the question has occurred to me several times to ask if the importance of their result might not be usefully extended over the agricultural world and their good more widely known than they are? I gladly lent the papers containing Mr. Smith's papers to both farmers and labourers as the best persons to be made acquainted with the welcome disclosures, but I am sorry to say with wretchedly unfruitful returns. I might as well have given them the Bible in the original tongue; men don't like to be dumfounded, and stubborn ignorance, ashamed, won't own its defects, so that my good intentions were baffled by bucolic stolidity and conceit, that, entrenched in old ways and self-love, refused to admit the innovations of science they could not understand. How slow is the progress of knowledge! Believing, as I still continue to do, that the primal cause of the complaint is the coarse treatment of the root in its mode of culture, permit me to ask if it would not be possible to popularise Mr. Smith's well-tested observations and results, totally dismissing all hard words or scientific terms, and finding their equivalent in easily appreciated English names, or even local ones render his remarks comprehensible to all? Such a work, I think, could hardly fail to be both individually and nationally common good, and "do yeoman's service," particularly if it laid the main stress on the value of insuring for the future a more cleanly and wholesome mode of culture? Unfortunately, the malady has become hereditary, and being established for forty years, its long malignant prevalence will be hard to eradicate or cure. My opinion is, that throughout England, Scotland, and Ireland the Potato is the victim of gross treatment, by applying the manure to it in too direct a manner. The Cornish mode of cultivation is as follows:—The workman digs a trench with a spade, and walks in the cutting as he progresses. The result of his labour is a shallow gutter, and, of course, detrimentally trodden down and hardened with his feet, and in its hollow the sets are placed at intervals, each part perhaps fresh cut, with unhealed wounds on the sets; the dabs of dung (or manure of some sort) are placed in the cutting, being smothered with corrupting festering filth, suggestive of a vegetable plague. I know no plant that would stand such treatment and live, and the wonder is that the Potato has not degenerated before. In making the next parallel, the earth that is dug out of the second groove is thrown over the first, and that row is complete. The manure used is a compound variety of all kinds of refuse that the locality can furnish, putting aside lime and guano as exceptional (though both are occasionally applied). The following dressings are most prevalent in the county. Deposits from muck-middens, a collection of house contributions thrown out daily, cinder-ashes, cow and horse dung, pig-dung, human faeces, urine, soot, street or road sweepings, all left to fester in a heap exposed to the sun! Near the coast seaweed is available, also sea-sand, often black and putrid (sometimes shelly) decayed fish, and the salt sweepings of pilchard cellars; all these ingredients dug in the ground and left to assimilate with it would be beneficial if put in three months before the plants, but applied to them when sown (as in the case of the Potato) the surprise is how the hardy tuber should have stood it so long. The result of my observations—unassisted by scientific research—is, that an impression has prevailed in my mind for some years that the evil of the disease is communicated by the Potato's early contamination with the manure, a deleterious applica-

tion of refuse, in which the root of no plant can be placed and survive—that is noxious to all vegetation, in the first festering fermentation of its decay, and in which ultimately, when its virulence has passed away, is shown its affinity for mildew and fungus, the first outgrowth of all mouldering corruption through the world. *W. Browne, Beach Cottage, Fowey, Cornwall.*

Lapageria alba.—I have forwarded for your inspection a bunch of *Lapageria alba* flowers. I have occasionally observed clusters of four or five flowers together, but never one so large as the one I have sent you, and I shall be glad to know if such have before come under your notice. Its production I attribute to the vigorous health of the plant. I planted it nine years' since, together with one of the best variety of rosea, in a span-roofed house 20 feet long, which have nearly covered the north side of the roof, and is now bespangled with these gaudy and strongly contrasted coloured flowers, the number of which can only be calculated by the hundreds and more probably thousands. It is a very general idea that *alba* is much more spare in its growth than *rosea*, which I do not find is the case when properly treated and careful watching of the growths when emerging from the roots. We have some which come to the surface of the bed during last spring, which at first appeared exactly like real good stocks or heads of Asparagus, which are now 28 feet in length, and probably will in November have some dozens of flowers on them. *R. Westcott, Raby Castle, Darlington.* [A truly superb specimen. Eds.]

An Interesting Conservatory Plant: Kniphofia Macowani (Tritoma Macowani).—I have a large stock of these blooming in 48 and 60 sized pots, the plants ranging in height from 1 to 2 feet, and with graceful slender foliage. Looking at the batch this morning I could not help feeling that those who are fond of characteristic plants in their greenhouse would find this an acceptable addition at the present season. I have not yet planted any out-of-doors, but purpose doing so next season. Herr Max Leichtlin considers it harder than *Tritoma glaucescens*, which has remained for many years in my grounds without protection. It is a free-flowering plant, and, from what I have said, you may judge of its grand effect as a border plant. I send you here-with specimens of the flowers, that you may judge. The beautiful rich soft orange spikes, with from twenty to fifty from an established stool, would be an object not to be despised in a mixed flower border, or associated with dwarf flowering shrubs in American borders or beds. *P. Barr.*

Mildew on Grapes.—A correspondent mentions, in the number for September 1, having heard of a case where "scraping off the bark" of mildewed Vines—that is, in the following season—was a "perfect cure." I have this season succeeded very fairly in saving a badly mildewed crop of Grapes in one house by wiping the berries about once a week for six weeks. The Grapes are quite saleable, and will be sold for the London market thus wiped. The bloom is gone, and they are not so large as usual, still they are ripening well, and are as fairly coloured this unfavourable season as many others not mildewed. I showed them to a good judge this week, to his immense surprise; and one importer on a large scale smiled at the notion of much bloom remaining on any Grapes by the time they reached their destination. If mildew remains even for a very short period unnoticed on Vines it will stain the shoots, but in the older wood this would hardly be perceptible. Why not try wiping the berries the moment you notice any mildew with soft muslin? If neglected, then wipe the leaves also and the wood. By painting the canes and shoots in the winter, and watching for any renewed symptoms next season, there is no reason why mildew should not be stamped out. Sudden draughts should also be avoided. These dry roots, with a cold, damp inner temperature, favour the introduction of this pest. Still there are mysterious causes besides these as yet unknown. *T. C. Fréhaut.*

Deutzia gracilis is a plant that is largely grown for the London market, and though there are many fine things that flower during the dull months of the year, I find the commoner things when well done are as greatly admired as the tenderest exotic, and a well done *Deutzia* in any sized pot is a very interesting object. In many places they are huddled together in any out-of-the-way corner, on the half-starved system, but when liberally treated, as they are by the grower for market, they soon make lovely objects in their wonderful 4-inch pots. They are easily propagated by cuttings and layers, but provision must be made according to the demand. If by cuttings, put as many into a 4 or 6-inch pot as possible, harden well off by May, shake all out of the pots, and plant them in well prepared nursery beds; if by layers, plant as many stools as will supply the requisite number of layers, peg the shoots all round the stock, next spring take them up and plant in nursery rows, and treat as

the cuttings: always replace those that are taken off by last year's growths; this system gives good healthy plants. The next spring cut them all back to within 3 or 4 inches of the ground, and pinch them back twice during the summer; the following February or March pot them in 4-inch pots in good loamy soil, and plunge in prepared beds of ashes or tan; during the summer pinch any shoots that show signs of grossness, keep well watered, and as the season advances give occasional waterings of liquid manure. About the end of October the preparation for forcing begins, by getting as many as possible under cover from the drenching rains and frosts, introducing them in batches into a nice heat of from 45° to 55°, shutting up early with plenty of moisture till they begin to show flower, then move into a dryer and cooler house to harden off for market. When grown for private establishments they can be grown on the same principle into any sizes, by cutting well back as soon as done flowering; give them a little heat to get a good break, harden well off, and plant out on prepared beds. By always keeping up a succession of young plants by cuttings or layers, it is not requisite to divide the old plants, which seldom give satisfaction. It is wonderful how long they can be kept in smallish pots, by plunging and liberal treatment. Lilacs, Primroses, Guelldres Roses, Callas, *Cytisus racemosus*, *Habrothamnus elegans*, &c., do well on the same treatment. The three latter ought to be taken out of the plunging material about the end of September. The plunging system saves a great amount of labour in watering. *E. W.*

The Roseless Autumn.—I believe your correspondent, Mr. D. T. Fish, is right, and I speak from what I see as well as from what I hear. Letters from large and experienced growers are reaching me from all parts of England reiterating his remarks. The growth after the summer blooming has been generally fitful and uneven, and there are more wood-shoots than usual, and consequently less flowers. *William Paul, Paul's Nurseries, Waltham Cross.* [In our own experience summer roses were destroyed by spring frosts, autumn roses have been most abundant. Soil, Middlesex clay. Eds.]

The Colorado Beetle.—Ever since I saw the cut of the Potato-bug in the *Gardeners' Chronicle* of July 28, I have been wishing to say that it is in every way quite natural except that the artist was too sparing with the bugs, as we consider five or six perfect insects, with twenty-five or thirty larvae (of different sizes) to the square inch, to be a fair average crop. But you will doubtless have abundant opportunity for observation in this line after his bugship has established himself upon your shores. I suppose you await his arrival with considerable anxiety, but doubtless England will rise to a man to expel the invader, in which case (if every man does his duty) the victory will be an easy one. I see that Paris-green is recommended for their destruction. I am not aware of anything having been discovered up to this date that is as efficient; 1 lb. of Paris-green to 25 lb. of rye or wheat flour, thoroughly intermixed and thinly sprinkled over the plants, is the usual method of application, and is much more economical both in time and material than mixing the Paris-green with water. Quite a large experience has taught me this. But this season I have adopted a still more economical method, as follows:—I have this season mixed Paris-green with common fine-ground plaster of Paris, in the proportion of 2 lb. of Paris-green to 250 lb. of plaster. This is applied to the plants by means of a fine flour-sieve, with a stick fastened across the top for a handle. This answers every purpose. It is fatal to the vermin, and every way satisfactory, and the advantages of plaster over flour are several:—1, cheapness; 2, being much heavier than flour it fixes the Paris-green, allowing none to escape on to the adjoining crops, and general safety in application; 3, two or three such applications of plaster during the season becomes a valuable fertiliser to the land. I have applied it twice to our crops of Potatoes, and have succeeded in making a thorough clearance of the bugs and larva at each application. *H. E. Chitty, Bellevue Nursery, Paterson, New Jersey, U.S.A.*

Hardiness of White-Flowered Plants.—I came lately upon a rather noticeable instance of the supposed superior hardiness of plants with white flowers over the same varieties with coloured flowers. I cannot say how far it is always the case. I do not know that I ever observed it before, though most flowers sometimes occur white. The charming *Solanum Dulcamara* is I think rather capricious as to soil, and here in Scotland it is not very common, though it grows luxuriantly in many places, but I have never seen it except near the sea, or nearly on a level with it. But lately passing for a good many miles through a corn country, where I rather missed it in the hedges, and certainly had not seen a single specimen, I was struck, on reaching the top of a ridge, exposed to the winds

as much as it could possibly be, and 200 or 300 feet above the sea some 8 miles off, to see the more sheltered bank of the road half-covered with the white-flowered variety of *Solanum Dulcamara*. I saw no signs of the common kind in the neighbourhood. *F. M., N. B.*

Striped Petunias Seeding.—I observe a query at p. 343 from a correspondent respecting the seeding of striped Petunias. My experience for several years has been that these Petunias are free seeders, especially towards the autumn after the plants have somewhat exhausted the soil and are making less growth. During September, especially if the weather be fine, they seed very freely. The striped forms having frimbriated edges, on the other hand, seed but sparsely, they make a very robust woody growth that is almost too luxuriant for the open ground except in poor soil. Striped Petunias, if a good strain, come very true from seed, and will make a most charming mass of mixed colours in a flower bed. *A. D.*

Sutton's Magnum Bonum Potato.—This Potato with me this season has withstood the disease better than any other variety grown here. A peck was purchased and planted in the ordinary way of field culture, making as many sets as possible. The crop was lifted to-day, and the produce from the 1 peck is about 8 bushels of large, handsome Potatoes, and not a single diseased one was found amongst them. When cooked it is of first-class quality. In the same field, right and left of *Magnum Bonum*, are ten other sorts planted, and I should say, as near as possible, half the crop are diseased. In all I grow a little over 3 acres, and the other sorts less diseased are *Early Don*, an excellent Potato; and the well-known *Dalmahoy*. Surely if any Potato will resist disease as *Magnum Bonum* has done, combined with productiveness and good quality, it is entitled to special notice and extended cultivation by all. *Thomas Carlton, Ashstead Park Gardens, Epsom.*

The Potato Crop of 1877.—Having had continued rain since July 14 in North Wales, it seems to touch upon the old proverb of forty days' rain. We have had considerably more than that, but have during the last few days had splendid harvest weather. The Potato crops at this place are most extraordinary, many of *Myatt's Prolific*, *Mona's Pride*, and others, weighing a pound each; but in all my experience of many years I never saw the disease so destructive as this year. It will be a very great loss to many of the large growers for market in the neighbourhood of *Llandudno*; we see whole fields completely dried up in the foliage. The last week or ten days, it matters not whether on the mountain or in the vale, all appear the same. *T. Capers.*

Orchard-house Experience.—I have just read Mr. Bréhaut's very interesting article on Orchard-houses, p. 334. I also am among the "early orchard-house workers." My trees came from Mr. Rivers in 1856. Mr. Bréhaut's houses appear to be not more than 15 feet wide, but he says, "as to ordinary span-roofed houses, I consider those of Mr. Rivers as of the best dimensions—say, 100 feet by 30." He also states, "Cherries and Apricots are impossible, save in immense houses—they need too much air." While entirely agreeing with most of Mr. Bréhaut's paper, I must demur to the last two propositions. I believe it to be true in practice, as it is in theory, that with most fruit the nearer the glass, and the freer circulation of air, the higher the flavour and the better health of the trees, and better setting of the fruit. The objection to narrow low houses is their little power of keeping out severe frost. I believe the best practice to be to have two houses, one for storing the more delicate fruit trees, such as Peaches and Nectarines, the other for placing them to ripen their fruit. Our plan is this—we grow Peaches, Nectarines, Apricots, Cherries, Figs, Plums, Pears, and Apples, to say nothing of the *Diospyros Kaki*. Almost all the trees are in pots, the first named five, except for a turn-out in autumn after the fruit is pulled; live in the houses, the others are only kept in till safe from frost, or, in the case of Plums, put in in wet weather, to prevent cracking. Our largest house is 60 feet by 20 in the clear, and 10 feet 6 inches high to the ridge-board, with raised middle bed as originally recommended. In this all the better-class fruit trees live, rather closely packed, through the cold weather. In the second house, 60 feet by 15, 6 feet 6 inches high to ridge-board, Plums, Pears, and Apples are huddled together till danger from frost is over, they are then turned out to make room for their betters. I believe in this low, narrow glass shed; where all the trees are close to the glass, and where the air circulates freely through their leaves better results are obtained than in any wide, high houses, especially with Apricots. Our Cherry trees live in the larger house. They always bear well, and from their earliness are amongst the most popular of the orchard-house productions. I used to wonder that orchard-houses were not very much more general.

I believe the reason why they seldom succeed in great gardens to be this. They require hard, constant work and attention, and there is much less honour and glory attached to them than there is to the growing of Pines, forced Grapes, Orchids, and stove plants, so a skilled, highly-trained gardener is apt to look down upon them. I believe the way to make them succeed is to put an under-man in charge, and lead him to take a pride in making a success. Our old trees, more than twenty years in pots, many of them subjected in old days to experiments, chemical and mechanical, and of shapes of which the less is said the better, give regular crops. I only remember one failure, that was with a cold, sunless spring, when the blossoms did not set (a neighbour who had the dangerous luxury of a hot-water pipe turned on heat and got a crop). Some of the Pear trees have the base of their trunks more than a third the diameter of the pot. They have arrived at the full weight for a man and boy to carry, and so can have no further shifts. So far they are in perfect health. I have more than once heard orchard-houses called toys, but as long as in a cottage garden, where our orchard-houses are, we get more and better fruit than is produced in most large gardens, I shall continue to think them very satisfactory toys to play with. *George F. Wilson.*

Rainfall in North Derby.—I have thought that a copy of the register of rainfall here (N.E. Derbyshire, bordering on North Notts), from September 1, 1876, to the end of August, 1877, may be acceptable to your readers, which though not a chronological year includes 365 days, out of which on 230 days .01 inch or more rain fell. I will quote each month separately, the number of days on which .01 or more rain fell with the date and amount of greatest fall in twenty-four hours, and total for each month. The monthly average is 3.576 inches, or a little over 3½ inches:—

	Days.	Date.	Depth.	Total.
1876.				
September	24	30	0.84	4.59
October	14	8	0.76	2.12
November	20	12	0.92	3.82
December	26	6	0.77	7.09
1877.				
January	24	3	1.31	3.93
February	21	25	0.76	2.42
March	21	24	0.65	2.60
April	19	9	0.64	2.69
May	16	10	0.54	3.24
June	9	1	0.80	2.01
July	16	14	0.87	2.93
August	23	25	1.25	5.41
	230			42.92

In this exceptional season from seed-time to harvest the husbandman has had much need of patience for the fine weather, rather than "for the early and latter rain." The average summer heat, too, has been very low, which, following a very cold spring, has made harvest unusually late. In respect to fruit we have shared the common lot; we had a good crop of Gooseberries and Currants on bushes sheltered by orchard trees—though light, the latter are nearly bare of fruit, with two or three exceptions in Apples, *Duchess of Oldenburg*, *Nonsuch*, and *Wellington*. We have a few Pears on walls of *Passe Colmar* and *Jargoeille*; the latter bloomed and had set its fruit before the very cold frosty winds came that cut off a splendid show of bloom on most other sorts, which confirms what has been often noticed before, that the young fruit can withstand more cold than the blossom, especially if accompanied by wet. The *Jargonelle* being an early bloomer frequently gets cut off when later blooming sorts have a good crop. By way of supplement to the above account of rainfall, I may add that we have had up to the 14th inst. 3.31 inch of rain this month, of which 1.55 fell on the 2d. Harvest operations are consequently very much impeded. The disease in Potatoes is developing itself very rapidly—some crops are nearly all bad. *R. Rolfe, Gr., Suffynwood Hall, near Mansfield.*

Notices of Books.

Arboretum Segrezianum. Paris: Baillière. Under this title M. Alph. Lavallée has published a classified list of the trees and shrubs grown on his estate at Segrez, near Paris. The collection dates from 1857, with the exception of a few fine old trees already in the park. The preface tells us of the difficulties experienced in grouping the trees and shrubs so as to place them in the situations best adapted for them. M. Lavallée's efforts have been rewarded by obtaining a nearly complete collection of all the species of trees and shrubs hardy in the centre of France. The total number of reputed species and varieties is estimated at 4267, not including mere garden varieties, of which about a thousand are grown. Of these

eighty-four are Monocotyledons, 4081 Dicotyledons, and about 160 have not been determined.

The nomenclature presented an enormous difficulty, and M. Lavallée tells us that in preparing specimens for the herbarium and for future identification, he found it the best plan to forget or to ignore the name under which he received the plant in question, keeping a record, however, of this name, the source whence obtained, the date of receipt, the place where planted, and other necessary details. In addition to catalogues and plans, each tree bears a provisional label, containing similar information, destined to be superseded by a permanent label when the correct name has been decisively made out. The difficulties M. Lavallée has had to contend with in maintaining these collections in proper order are greater than those encountered in forming the collections. Without rigorous accuracy, continual revision, infinite precautions that each species should be represented by numerous examples, it would have been impossible to have preserved order amid so large a number of plants. In the formation of his arboretum, M. Lavallée has had the assistance of M. Herincq and of M. Decaisne, so that the correctness of the nomenclature may be relied on. An herbarium, a collection of books and plates relating to trees, a museum for specimens of woods and fruits, have all been established at Segrez, and have resulted in the present catalogue, acknowledged to be imperfect, but likely to be of great service in promoting the correct nomenclature of trees, and in unravelling their intricate synonymy. Gardens and nurseries, says M. Lavallée, abound in imperfectly known species. Many reputed common do not exist in cultivation; others, supposed to be rare, exist in profusion. Of these errors and misapprehensions M. Lavallée cites several instances which are familiar enough to all who make collections of living plants.

M. Lavallée brings a rather serious charge against *quelques horticulteurs* of purposely changing the name of old and long-cultivated species, and applying to them some new name. We do not believe that such a practice is wilfully followed in this country, unless in quite exceptional cases. Another cause of complaint brought by the author against nurserymen is that if they are applied to for a particular species not in their collection, they do not scruple to send something else, possessing none of the attributes of the required species but the name; thus in a plantation of twenty-six *noyers* (Walnuts) only two were correctly named.

M. Lavallée gives some interesting details relating to former collections of trees and shrubs in France. One of the most remarkable was that of René du Bellay, Bishop of Mans, established at Towvoive, and which formed the object of the praise of the botanist Gesner. This collection owed much to Pierre Belon, a physician and traveller of the period (1558). Of these collections not a trace now exists, and even the records of the bishopric were destroyed in the first French Revolution. From the mention of this the first arboretum in France the author passes on to the history of the *Jardin des Plantes* (which has been given in our columns) and to that of several other establishments, devoting, as is most due, some little space to the labours of Duhamel. The arboretum formed by this noted arboriculturist was situated at Vignay and de Monceau. His brother at Denainvilliers seconded his efforts, so that in 1755 appeared the first instalments of the *Traité des Arbres et Arbustes qui se cultivent en France*—a work not completed till fifty years later by Loiseleur-Deslongchamps, but a veritable monument of French learning and industry. Passing over other names and establishments of minor interest to us on this side of the Channel we come to the names of Michaux, whose work on North American trees is still of very great value. The Michaux, father and son, introduced a large number of American trees to France. In 1810 De Vilmorin established at Des Barres an arboretum comprising some 260 species suitable for forestry purposes. This collection is now the property of the State. About the same time the great tree nurseries of Audibert at Tarascon, Baumann of Bollwyllyer, André Leroy at Angers, and Simon at Metz, were established. Incidentally the author laments the too frequent dispersal of private collections at the death of the founder, and to more than one the epithet *saccage* during some political disturbance or other has unfortunately been applied.

M. Lavallée's sketch of the history of arboriculture applies almost exclusively to those in the neighbourhood of Paris, or at such a distance from the metropolis as to enjoy a similar climate. From what we

have said it will be seen how much of interest attaches to the details given by M. Lavallée, an interest so great that we could wish M. Lavallée would expand the brief sketch here given, and publish a general history of French arboriculture, using the word in the sense in which it is employed in this country. Of the intrinsic merit of such a list as M. Lavallée has given us there can be no two opinions—each species mentioned, with the authority for the name, the native country, and the synonyms. Use, not mere casual inspection, must determine the relative value of this catalogue, but it is quite certain that all tree lovers owe a debt of gratitude to the compiler for this valuable list. Incidentally we may remark that *Vitis Veitchii* (*sic*) was published in these columns soon after its first introduction. It is the *Ampelopsis tricuspidata* of Siebold and Zuccarini, and the *Ampelopsis Veitchii* of the nurseries. *Cissus Roylei*, often confounded with it, is sufficiently distinct in character, and comes from a different country. Under *Acer* we find no mention of *A. Schweideri*, under *Pyrus* or *Eriobotrya* no mention of *P. Maulei*, under *Vitis* no mention of orientals, under *Quercus* no mention of *Q. pannonica*, under *Thamnocalamus Falconeri* no hint is given that this is the plant generally, but incorrectly, known as *Arundinaria falcata*. *Q. nobilis* should be referred to *Q. nigra*. The references to figures and descriptions are also not so numerous as they might be. A more complete search through the horticultural and botanical publications would have enabled the author to add many more citations and references to figures, and which would have considerably augmented the value of his catalogue.

Taking it, however, as a whole, we can but express the gratitude of lovers of trees and shrubs, and trust soon to see a reissue in a more complete form.

Stock and Share Investments. By Albert Sharwood, *Bazaar Office*.—A little pamphlet containing just the information that is required by small investors, and which, if perused, may save much disappointment, not to say misery.

PUBLICATIONS RECEIVED.—*Scotch Live Stock*, by James Bruce (Edmonston).—*Victorian Year-Book for 1875*.—*The Clematis as a Garden Flower*, new edition, by Thomas Moore and George Jackman.—*Journal of the British Dairy Farmers' Association*.—*The Royal Guide to the London Charities for 1877*, by Herbert Fry.—*The Tannahill Bouquet*, by William Elder.—*Le Journal des Roses*.

Reports of Societies.

Brentwood Horticultural: September 6.—This society held their autumn exhibition in the grounds of Hampton House, by kind permission of the liberal proprietor, W. A. Ogg, Esq., who also lent his grounds for the spring show. The competition was generally abundant and the productions good. Especially pleased were we to see the numerous vegetables staged—and that more particularly in the cottagers' classes. Prizes which were offered for "miscellaneous stove and greenhouse plants, foliage plants, and Ferns, arranged for effect," were won by collections of plants far beyond the average in such classes. Here instead of massing for effect somewhat small plants in groups, as is generally done, the competition was carried out in each instance with the best specimen plants arranged single and in two rows, as is the case when a given number of stove or greenhouse plants are asked for. D. McIntosh, Esq., Havering Park (gr., Mr. W. Bones), won the 1st prize, having excellent specimens of *Encharis amazonica*, *Bougainvillea glabra*, *Allamandas*, *Erica æmula* (an excellent specimen), Ferns, &c. Major-General Fytche, C.S.I., Pyrgo Park, Havering (gr., Mr. Lane) was a good 2d, with amongst others a fine specimen and well bloomed of *Phenocoma prolifera* Barnesii, *Croton undulatus*, *Adiantum farleyense*, Palms, &c. W. A. Ogg, Esq., Hampton House, was also a very excellent 3d, his plants being larger, though both the 2d and 3d prize plants were greatly wanting in flowers compared with their more successful competitor. Mr. Rank, Brick House, Rainham, staged some thoroughly well bloomed double Zonal Pelargoniums. The six Pelargoniums for beauty of foliage brought out some splendid collections, all of which were of a very high order of merit. Mr. Meadmore, Romford, was placed 1st—Messrs. T. Hill, Brentwood (W. North, gr.), and Saltmarsh, Chelmsford, being respectively 2d and 3d. Fuchsias were well shown by W. A. Ogg, Esq. (Mr. Wise, gr.). The best arranged baskets of pot plants were won by the three nurserymen, Messrs. Saltmarsh, Ford, and Meadmore, in the order here given.

Cut flowers were very numerous and good, For

twenty-four Dahlias, Messrs. Saltmarsh (1st) and Rawlings (2d) deserve every praise, their stands being very highly finished, Mr. Rawlings had the largest blooms, but the finish of those of Messrs. Saltmarsh was so good as to warrant the award. Mr. J. C. Quennell, of Brentwood, won the 3d prize well as an amateur. For twelve Dahlias, Messrs. Quennell, E. Mitchell (W. Harrington, gr.), stood respectively 1st and 2d. Mr. Atkins, Warley, was 1st with Roses, good for the season. For twelve Asters, quilled and not quilled, respectively, Messrs. Saltmarsh received 1st prizes. Their stands were splendidly grown and staged. Messrs. Harrington and Atkinson had the best amongst amateurs. The best basket of cut flowers came from Mr. Quennell, showing real taste in arrangement. The winners of the Maiden prizes for vase of cut flowers were, the Misses Wise 1st, and Soder 2d. For the prizes offered for table decorations (open) Mrs. Burley showed a splendid arrangement. Using more flowers than is customary, her display, though light and elegant, was one of the gayest we have yet seen, yet being within the legitimate margin of taste without overcrowding. Mrs. Bailey, Brentwood, was an admirable 2d; indeed, for an amateur, we have rarely seen better taste displayed, the only fault, if any, being that the flowers used were somewhat too dull. This the best taste possible failed to neutralise. Miss Haws won the 1st prize for bouquets.

Fruits were tolerably numerous in all but Melons and Pines. For best collection of six kinds, Pines excluded, D. McIntosh, Esq., was 1st, Major-General Fytche being 2d; the Grapes in Mr. Bone's collection being large in bunch. Major-General Fytche also carried premier awards for black Grapes and Muscats. Fine Peaches were shown by Mr. Clark, Figs and Plums by Mr. Constable, a grand dish of Cox's Orange Pippin Apples by Mr. T. Simpson, Chelmsford, &c.

For a collection of nine sorts of vegetables Mr. J. Rank was 1st, and for six sorts Mr. Soder—the Onions, for weight, of the latter exhibitor being very fine.

Mr. Burley, nurseryman, Brentwood, received an extra prize for a large collection of plants, including large baskets of the chaste new Pelargoniums Miss C. Quennell, white variegated foliage, and light blooms with salmon eye; *Boadicea*, similar in habit, &c.; Mrs. Hanbury, and the popular *Snowdrift*. *W. E.*

Wellingborough Horticultural: Sept. 7.—This, one of the great centres of the shoemaking industry, dressed itself out with becoming taste on the occasion of the above exhibition; archways were thrown across the street, and many of the houses put on quite a festive appearance. It was held in a field in the town, and a thoroughly good show rewarded the labours of the promoters.

In the classes open to all England, stove and greenhouse plants were nicely represented, the lateness of the year considered. The best group of twelve, for which a handsome 1st prize of £10 was offered, came from Mr. J. Parker, nurseryman, Rugby, who had *Statice imbricata*, *Vinca alba*, *V. rosea*, *Dipladenia amabilis*, *Clerodendron Balfourianum*, *Allamanda Hendersoni*, *A. Schottii*, *Cycas revoluta*, *Allamanda nobilis*, &c.; 2d, Mr. J. House, nurseryman, Peterborough, who was strong in fine-foliage plants, but generally weak in those in bloom, the best specimens being *Phormium tenax variegatum*, *P. Colensoi variegatum*, *Croton interruptus*, *C. pictus*, *Allamanda Hendersoni*, and *Lantana borbonica*. In the class for six foliage plants Mr. House was 1st and Mr. P. Daventry 2d. With six Palms—very fair examples of good kinds—Mr. Parker was 1st and Mr. House 2d. With six new plants Mr. J. Parker was placed 1st, with *Cupania filicifolia*, *Ixora Williamsii*, *Phyllanthus niveosus*, very nicely variegated; *Croton majesticus*, *C. Youngi*, and *C. Weismanni*. 2d, Mr. J. Jackson, Blakedown Nursery, Kidderminster, who had *Croton Weismanni*, *C. Disraeli*, *C. Youngi*, *Cocos Weddelliana*, *Livingstonia Jenkinsii*, and *Aralia elegantissima*. Exotic Ferns, as well as hardy kinds, were moderately shown.

In the cut flower classes, Mr. W. Corp, nurseryman, Oxford, set up a stand of forty-eight Roses of excellent quality from the seedling Brier, and it would appear that if autumnal Roses are to be had this stock must be mainly relied on for the purpose. The best flowers were Madame Hunnebelle, Sir Garnet Wolseley, Madame H. Jamain, La France, Duc de Rohan, Pierre Notting, Belle Lyonnaise, Marie Foger, Madame Laurent, Marie Rady, Paul Néron, Avocat Duduvier, François Michelon, Horace Vernet, Beauty of Waltham, Star of Waltham, and Marie Van Houtte; 2d, Mr. J. Bond, with some very fine flowers. Mr. Cross was 1st in two other classes, and in that for twelve Tea-scented and Noisette Roses he set up very charming examples of Marie Van Houtte, Bouquet d'Or, Madame Bernard, Belle Lyonnaise, Devenionsis, and Louise de Sarvie among others. The best thirty-six Dahlias came from Mr. P. Painter, Smallwood, and included fine blooms of Annie Delevanté (large white), Criterion, Vice-President, Mr. Saunders, Royal Queen, Perfection, Yellow Globe,

and Royal Purple; 2d, Mr. W. Jackson, Kidderminster; 3d, Mr. G. H. Feukes, Erdington.

The other divisions of the schedule were, to a great extent, a repetition of the foregoing classes, but as far as the exhibits were generally concerned in descending scales of quality; but a good effect was secured, and the four commodious tents were completely filled.

The best collection of six dishes of fruit came from Mr. G. Day, Daventry, and consisted of good White Muscat and Black Hamburg Grapes, Peaches, Nectarines, Melons, and Morello Cherries; 2d, Mr. W. Watts. Mr. Day also had the best three bunches of white Grapes, consisting of Duke of Buccleuch, Bowdoin Muscat, and Muscat of Alexandria; and the best three bunches of black Grapes also, in Black Hamburg, Alicante, and Lady Downe's.

The best collection of eight kinds of vegetables came from Mr. T. Eads, gr. to J. Becke, Esq., Northampton, and consisted of fine Cauliflowers, Carrots, Beet, Turnips, Porter's Excelsior Potatoes, Onions, and Cucumbers—a remarkably good even lot; 2d, Mr. G. Day, with a very good lot also; and the six collections staged in this class were highly creditable. In all the classes vegetables were finely shown. An extra prize was awarded to Mr. T. Eads for an excellent collection of ten dishes of Potatoes, consisting of Fenn's Perfection, Snowflake, International Kidney, very fine; Bountiful, Waterloo Kidney, King of Potatoes, Model, Emperor, Porter's Excelsior, and Schoolmaster.

Hardy fruits were well represented, the culinary and dessert Apples being remarkably good. A pretty Apple, named Lord Lennox, was much shown as a dessert variety.

Collections of wild flowers were in pretty bunches of distinct sorts, shown as they should be. Bouquets of wild flowers were also very attractive. Collections of Grapes were similarly shown as the wild flowers, and two sisters, Ellen and Emily Coles, had the leading prizes in both classes. Designs in wild flowers were in the form of gardens to villa residences.

Factory Hands' Flower and Vegetable Show at Guide Bridge.—We are again able to speak in terms of commendation of the results of the cottage horticulture set on foot some few years ago by Mr. Hugh Mason in connection with his great cotton mills at Guide Bridge, 7 miles from Manchester. Closely adjacent to the mills there are more than a dozen nice little gardens, separated by hedges and paths, and let, at a merely nominal rent, to such of the workpeople as have an aptitude for the cultivation of flowers and vegetables, and who through good conduct or long service are entitled to claim priority in the privilege of possession. The most cordial encouragement is also given to the cultivation of pot plants in the windows of the workpeople who live around, so that on approaching the mills the spectacle of domestic leaf and flower is most refreshing. Why cannot every great mill-owner in the country follow this good example! If it were only for appearance sake how much good might be effected by the placing in every cottage parlour in the land of some pretty flowering plant, or little shrub. A flower in the window sweetens the air, makes the room look graceful, gives the light of the sun as it shines through it a new charm, and helps to develop love of neatness, cleanliness, and order.

Mr. Hugh Mason's factories are called the Oxford Mills, and familiarly, in the neighbourhood, Oxford. The Oxford gardeners, with others of the workpeople who reside near, and who have independent gardens of their own—the latter formed under the inspiration of what is done close to the mills, have constituted themselves into a little horticultural association, not with a view to any public display, but purely for the sake of good fellowship and co-operation. Under Mr. Mason's influence every year, about this time, a show is held of the best of the produce, both garden and window, and very pretty and creditable the display has always been. The show is held in the lecture-room of the Oxford Institute, which building, we may remark, erected by Mr. Mason at his own cost, is one of the completest things we know of in regard to its providing for every kind of rational human want. There is a capital library, with news-room, of course; there are baths also, and at a little distance, in outdoor supplement, there is a spacious drying-ground for the women who work in the laundry, and a bowling-green for the men. The whole place has an air of cleanliness, neatness, and finish, such as it is seldom our good fortune to meet with in the neighbourhood of a large manufacturing establishment. The current year's show came off on Saturday, September 1, and was quite equal to any of its predecessors, though in some respects declaring only too plainly the hurtful character of the recent weather. Not to mention the incessant rain, the Oxford gardeners have this year had an uncommon plague of caterpillars. The most effective of the vegetables were the Cauliflowers, all very good and meritorious. It was natural, however, that the greatest amount in prizes should go to a vegetable of humbler description—the immemorial

Onion, which was excellently done both in purple and white. Besides these, there were Potatoes, Greens, Carrots, Peas and Beans, Cucumbers, salad plants and seasoning herbs. The Oxford gardeners, of course, cannot have it all their own way. They succeed least satisfactorily perhaps with their Peas. Gardening, wherever carried on, like all other human enterprises, of course, has its failures and disappointments. It tries not only one's powers of perseverance, but one's patience and one's faith. Still, in the most ill-favoured of localities, and in the worst of seasons, there is always plenty to rejoice in, and more that gratifies than disappoints, and this we take to be one of the best facts or principles connected with the promotion of horticulture for the million, especially in and near our great manufacturing centres. The trials, the hopes and fears, the rewards and discomfures connected with gardening, constitute a very salutary part of education; and as the truest and best results of education, rightly so-called, are shown to men becoming more manly and self-reliant, more content and more generous, it follows that a garden is one of the best schools of moral discipline. A cottage garden is not only a source of wholesome vegetable food, it does good to a man's whole character. The prizes awarded at Oxford consist, not of money, but of useful household articles, rocking-chairs, kettles, knives and forks, &c., so that all in the family may participate. This is very wise, as it shows to all the home circle that the idea of a garden is never intended to be selfish and exclusive, but in one way or another promotive of the pleasure and welfare of all who are connected with it. The idea of a selfish garden is one of the most shocking and inconsistent things in the world. Every man, of course, has a right to do what he likes with his own—provided he likes to do with it what is right, and that which is right can never be done with a garden if, in one way or another, God's good gifts, as displayed in it, are not opened to the enjoyment of many. The window plants comprised chiefly Fuchsias, Pelargoniums, Vallotas, Agapanthus, and Japan Lilies, all very pretty and delightful to look at, the more so because so certainly the recipients of plenty of human care, for that they had been tended well-nigh as carefully as a child was quite evident. Herein is found another good use of cottage window-gardening—it tends to awaken kindly sympathies, and with these to improve the taste. The cut flowers consisted principally of Dahlias, scarlet Gladiolus, Asters, Antirrhinums, and French Marigolds, with a sprinkling of Carnations. A tray of Roses, from somewhere close by, was also very creditable. Fruit, of course, could not be expected in quantity. Some of the Oxford gardeners have little greenhouses, in which they manage to raise a few Grapes. We would recommend them, with the kindest recognition of their industry and their desires, to try instead of Vines a *Maréchal Niel* Rose, for the blooms of which they would find a good market in the town, and thus add to their pecuniary profit. For the sake of decoration, Messrs. Taylor Bros. sent 150 ornamental tender plants; and Mr. John Shaw, jun., of Bowden, a quantity of Palms and Cycads.

The Oxford Institute supports a band, which at intervals "discoursed sweet music;" and at an appropriate hour an address was given by Mr. Leo Grindon, of Manchester, on the origin, history, &c., of the best descriptions of fruits at present cultivated in Great Britain. We cannot speak in terms too high of the practical value of the work thus set going by Mr. Hugh Mason, with results already so marked. The example is worthy of imitation wherever an employer has generous instincts, and if it cannot be carried out on a scale so extensive as at Guide Bridge, it can at all events be tried on a smaller one, improving and extending by degrees.

Prizes are given, we must not forget to add, for the neatest and best-kept gardens. They were awarded, on this occasion, to Wm. Whittaker, Joseph Bridge, and Thomas Moss. Commendation was also given to J. A. Isherwood. (From a Correspondent.)

Stevenage Horticultural Society: Sept 14—The usual autumn exhibition of this Society took place in the Town Hall on the above date, and was one of the best exhibitions the Society has held for some time past. Particularly does this remark apply to the cottagers' produce, which is the more satisfactory as the real object of the Society is to give encouragement to the many cottage and allotment gardeners in Stevenage and the surrounding villages covered by the operations of the Society. The cottagers' productions as a whole were in advance of those shown by amateur and professional gardeners.

In the class for a single plant in a pot not less than twenty-two plants were staged; the best was a remarkable *Hydrangea*, showing indisputable signs of window growth—a large, well-grown, healthy, clean, bushy plant, having seven large trusses of bloom. This came from Henry Baldry. Next in importance came some good specimens of *Vallota purpurea* in bloom, *Fuchsias*, *Coleus*, a well-grown *Gladiolus*

in a pot, &c. The collections of wild flowers arranged with taste were remarkably good; and the sauce and table Apples excellent. The basket of mixed vegetables shown by W. Hough, to which the 1st prize was awarded, was some way in advance of those shown by amateurs. The cottagers' vegetables were remarkably good, and, with the exception of the Vegetable Marrows, were such as any gardener might have sent to his employer's kitchen.

In the amateurs' and general classes the leading exhibitors were Colonel Metcalfe, C.B., Ashton House; the Rev. J. O. Seager, Stevenage; and the Rev. J. F. G. Jenyns, Knebworth; the Rev. J. E. Pryor, Bennington; Lieut.-Colonel Wilkinson; Mr. G. H. Smith, Stevenage; G. Salmon, Esq., &c. The Rev. C. E. Segar had the best basket of fruit as well as the best bunch of Grapes. Mr. G. Salmon's stand of twelve Dahlias was highly creditable, and the Asters from Colonel Metcalfe, C.B., remarkably good.

Desert and culinary Apples were numerous and fine, and in the former the Rev. W. Jowitt staged a good dish of Early Codlin. Among vegetables, Potatoes and Celery were specially fine.

The plants comprised miscellaneous groups, also *Fuchsias*, *Coleus*, *Balsams*, &c.; all fair for a locality in which outdoor rather than indoor gardening appears to be most generally followed.

A leading feature is the baskets of mixed vegetables in the general class. On this occasion the best came from G. Salmon, Esq., and second best from Captain Fellowes. We were sorry to learn from the active honorary secretary, Mr. George Dunn, that the necessary support to maintain two exhibitions yearly is declining. The Society depends mainly on annual subscriptions for support, for the proceeds in the way of gate-money are very poor indeed; and it would be a decided calamity were the shows to be discontinued through lack of public support, for they have done much to improve the social position of many of the cottagers.

- Sept. 13.—A dull, stormy day. Occasional slight rain. Gale at times.
 — 14.—Overcast, dull, and windy throughout. Slight shower of rain at 2 P.M.
 — 15.—Generally fine, dull at times. Showery in morning.
 — 16.—Dull and foggy till 11 A.M., fine and bright after. Cool.
 — 17.—Fine, but dull and cloudy. Cool breeze.
 — 18.—A fine day, partially cloudy. Cold.
 — 19.—Overcast and dull throughout. Few drops of rain at 5 P.M.

LONDON: Barometer.—During the week ending Saturday, September 15, in the vicinity of London the reading of the barometer at the level of the sea increased from 29.99 inches at the beginning of the week to 30.04 inches by the morning of the 10th, decreased to 29.75 inches by the afternoon of the 11th, increased to 30.03 inches by noon on the 13th, decreased to 29.80 inches by the morning of the 15th, and increased to 30.18 inches by the end of the week. The mean reading for the week at sea level was 29.95 inches, being 0.07 inch below that of the preceding week, and 0.13 inch below the average.

Temperature.—The highest temperatures of the air observed by day varied from 71½° on the 11th to 63½° on the 10th and 15th; the mean value for the week was 66½°. The lowest temperatures of the air observed by night varied from 49° on the 9th to

59° on the 14th; the mean for the week was 53½°. The mean daily range of temperature in the week was 12¼°, the greatest range in the day being 18½°, on the 11th, and the least 7½°, on the 15th.

The mean daily temperatures of the air, and the departures from their respective averages, were as follows:—9th, 56° 7', -1° 4'; 10th, 56° 2', -1° 8'; 11th, 60° 6', +2° 8'; 12th, 59° 3', +1° 7'; 13th, 58° 3', +0° 9'; 14th, 61° 6', +4° 4'; 15th, 59° 2', +2° 1'. The mean temperature of the air for the week was 58° 8', being 1° 2' above the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 128° on the 9 h, and 114° on the 12th; on the 14th it did not rise above 71½°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 45° on the 15th, and 45½° both on the 9th and 13th. The mean of the seven low readings was 48°.

Wind.—The direction of the wind was variable, and its strength brisk. The weather during the week was dull, and the sky cloudy.

Rain fell on four days during the week; the amount measured was 0.17 inch.

ENGLAND: Temperature.—The highest temperatures of the air observed by day were 72° at Cambridge, and 71½° at both Blackheath and Nottingham; the highest temperature at Bradford was 62½°; the mean value from all stations was 67°. The lowest temperatures of the air observed by night were 40° at Cambridge, 41° at Hull, and 41½° at Eccles; the lowest temperature at Truro was 53°; the general mean from all stations was 47°. The range of temperature in the week was the greatest at Cambridge, 32°, and the least at Plymouth, 12½°; the mean range of temperature from all stations was 20°.

The mean of the seven high day temperatures was the highest at Cambridge, 69°, and at Blackheath and Norwich 66½°, and the lowest at Bradford, 60½°; the mean value from all stations was 63½°. The mean of the seven low night temperatures was the lowest at Eccles, 48½°, and Wolverhampton, 49½°; and the highest at Truro, Brighton, and Plymouth, all 56°; the general mean from all stations was 52½°. The mean daily range of temperature in the week was the greatest at Cambridge, 18°, and the least at Plymouth, 5½°; the mean daily range from all stations was 11½°.

The mean temperature of the air for the week from all stations was 56½°, being 5¼° higher than the value for the corresponding week in 1876. The highest was 59½° at Brighton, and the lowest 54½° at Wolverhampton and Bradford.

Rain fell on four or five days in the week at most stations. The amounts varied from 2 inches at Hull, and 1½ inch at Bristol and Plymouth, to one-tenth of an inch at Norwich; the average fall over the country was 1 inch.

The weather during the week was generally dull and showery, and the sky cloudy. Lightning was seen at Liverpool on the 11th inst.

SCOTLAND: Temperature.—The highest temperatures of the air observed by day varied from 67½° at Edinburgh to 62° at Perth; the mean value from all stations was 64½°. The lowest temperatures of the air observed by night ranged from 35° at Paisley to 42° at Greenock; the mean from all stations was 39°. The mean range of temperature from all stations was 25½°.

The mean temperature of the air for the week from all stations was 54½°, being 3° higher than the value for the corresponding week in 1876. The highest was 55½° at Glasgow, and the lowest 53½° at Paisley.

Rain.—The falls of rain varied from 2½ inches at Greenock to six-tenths of an inch at Edinburgh, Aberdeen, and Leith. The average fall over the country was 1 inch.

DUBLIN.—The highest temperature of the air was 67½°, the lowest 40½°, the range 27°, and the mean 57½°. The fall of rain was 1.16 inch.

JAMES GLAISHER.

Variorum.

PRICES OF TIMBER IN KENT.—The annual sale of Oak timber, blackrinds, and Oak-top faggots upon the Surrenden-Dering estate, in the parishes of Pluckley, Little Chart, Snauden, Westwell, and Bethersden, took place on the 26th ult., when about 180 lots were submitted to public competition by Messrs. Bayley & Son, of Ashford. The timber was not of the class usually offered on this estate, as most of the last winter's falls of underwood, from which the thinnings are made, were upon the inferior woods of the estate. The company was, however, a large one, and the sale correspondingly brisk. The Oak timber ranged in price from 15. 6d. to 2s. 8d. per foot; blackrinds from 2s. 6d. to 9s. each; and Oak-top faggots from 25s. to 30s. per 100. The terms of pay-

ment in this locality are, for purchases of less than £5, prompt cash; £5 and upwards, half the purchase-money at the time of the sale, and the remainder early in October. The demand for timber of all kinds has been good throughout the season. Hop-poles have not, however, attained the prices of former years. Norwegian Fir poles, so extensively used in the best Hop plantations for lows, and for carrying the wire and string now employed in Hop-growing, have commanded very high prices upon the Maidstone and Faversham wharves. Ordinary home-grown hop-poles have realised from 10s. to 36s. per 100, according to length and quality of wood. Ash and Sweet Chestnut have been much sought after. *A. J. B.*, in "Journal of Forestry."

PHENOMENA OF LIFE.—Sufficient knowledge has now been acquired of vital phenomena, to justify the assertion that the notion that there is anything exceptional about these phenomena receives not a particle of support from any known fact. On the contrary, there is a vast and increasing mass of evidence that birth and death, health and disease, are as much parts of the ordinary stream of events as the rising and setting of the sun, or the changes of the moon; and that the living body is a mechanism, the proper working of which we term health; its disturbance, disease; its stoppage, death. The activity of this mechanism is dependent upon many and complicated conditions, some of which are hopelessly beyond our control, while others are readily accessible, and are capable of being indefinitely modified by our own actions. The business of the hygienist and of the physician is to know the range of these modifiable conditions, and how to influence them towards the maintenance of health and the prolongation of life; the business of the general public is to give an intelligent assent, and a ready obedience based upon that assent, to the rules laid down for their guidance by such experts. But an intelligent assent is an assent based upon knowledge, and the knowledge which is here in question means an acquaintance with the elements of physiology. It is not difficult to acquire such knowledge. What is true, to a certain extent, of all the physical sciences, is eminently characteristic of physiology—the difficulty of the subject begins beyond the stage of elementary knowledge, and increases with every stage of progress. While the most highly trained and best furnished intellect may find all its resources insufficient when it strives to reach the heights and penetrate into the depths of the problems of physiology, the elementary and fundamental truths can be made clear to a child. *Professor Huxley in the "Society of Arts' Journal."*

Enquiries.

He that questioneth much shall learn much.—BACON.

205. **CORDONS.**—Will any of your correspondents kindly favour me with their experience as to the angle at which Pear trees are best trained to wires in diagonal cordons? I observe Mr. Rivers, in his Catalogue of Fruit Trees, 1876, fig. 5, p. 4, has a woodcut showing a tree trained at an angle of 45°; while further on, p. 39, fig. 23 shows two trees trained at an angle of 60°. My trees have been planted and stood a few years at an angle of 60°; if it is likely that a less angle would produce fruit better in quality or quantity I would alter the angle, which I should not feel inclined to do without a fair prospect of improvement. *Cordon.*

206. **LADY HENNIKER APPLE.**—Will any of your readers kindly inform me if they have fruited the Lady Heniker Apple, and if they think it suitable for a market gardener to plant? *G. H. K.*

207. **HAUTOIS STRAWBERRY.**—I cannot get these to fruit. What management is necessary? *B.* [It is well known that many Strawberries are practically unisexual, even if both sexes be apparently present. Probably the male plants are deficient in your plantation. *EDS.*]

ANALYSIS OF FLOWERING PLANTS: *G. N. T.* Of course the composition depends not only on the particular flower but on the circumstances under which it is grown. See *Watts' Dictionary of Chemistry.*

CARLISLE SHOW.—Messrs. James Dickson & Sons, Newton Nurseries, Chester, write that they were awarded the 1st prize for a pair of Tree Ferns, *Dicksonia antarctica*, and obtained a First-class Certificate for a new variety of *Cyprinus Lawsoniana*. The same firm exhibited a general collection. Under no circumstances can we undertake to mention all the awards, least of all when a telegraphic report has to be sent us as we are going to press.

CATERPILLAR: *T. C. H.* The insect had escaped from the box.

DAHLIAS AT THE ALEXANDRA PALACE.—Messrs. Rawlings write that the flower with a pin in it, which was the subject of some comment at this show, was

not exhibited by them, as might be inferred from a passage in our report.

EGG-FRUIT DISEASE: *E. H.* The diseased fruit of the Egg-fruit was completely traversed by the mycelium of some fungus, probably belonging to some common mould; such cases are frequent.

FUNGUS ON VIOLET LEAVES: *W. C. B.* Your Violet leaves are attacked by a minute fungus, *Septoria violae*. It is one of those pests against which there is no remedy. The spores are extremely minute and multitudinous. Pick the infected leaves and burn them. We fear, however, it is too late, and the weather is highly favourable for their development. We have something closely allied from Scotland, if not identical. *M. J. B.*

GREENHOUSES: *J. Parrott.* We believe they are rateable, but as varying circumstances sometimes affect these legal matters you had better consult your solicitor.

INSECTS: *W. T. T.* The whitish objects on the seed-heads of Rush are the cases of the larvae of a very small moth (*Coleophora cespitiella*). They are universally abundant on Rushes; the larvae feed upon the seeds, and carry the cases about with them when they move from one capsule to another. We fail to find the "very small, pale brown cocoons," unless some loose seeds of the Rush represent them. *R. McL.*

LEAVES FOR GARNISHING PURPOSES: *Olivia.* The plant you mean is probably *Farfugium grande*. In winter you must take what you can get. *Aucuba*, *Mahonia*, *Magnolia*, and other evergreens will do best. If you have access to a shrubbery you only further require common sense and taste.

OAK SPANGLES: *T. E. Budman.* Very common in all seasons, but more than usually abundant this year.

FIG. 75.—OAK SPANGLES; 3 AND 4, SILK-BUTTON-GALL.

They are the work of a gall insect, a species of cynipis. (See fig. 76.)

NAMES OF PLANTS: 1, *Escallonia macrantha*; 2, *Nepeta Mussinii*; 3, *Capsella Bursa-pastoris* (Shepherd's Purse).—*Subscriber, Co. Down.* 2, *Gentiana asclepiadea*; 3, *Silene valesia* (?). The others, the numbers of which are obliterated, are *Dianthus deltoides* and *Teucrium Chamædris*. Write the numbers on paper in future.—*K.* *Coccoloba platyclada*.—*W. B.* 5, *Mesembryanthemum deltoides*; 6, *M. echinatum*.—*J. G. M.* *Escallonia montevidensis*; propagated by layers and cuttings.—*Enquirer.* A species of *Sanguisorba*. If wild, it is *S. officinalis*; otherwise it is probably *S. media*, but the specimen is insufficient.—*L. M. S.* *Actæa spicata*.—*E. L. A.* The Fulham Oak.—*F. S. C.* *Mentha arvensis*.—*T. S. Newry.* 1, The wild Scotch Rose, *Rosa spinosissima*; 2, apparently a *Lespedeza*, but the materials are insufficient.—*No Signaturæ.* 1, *Colutea arborescens*; 2, *Francoa ramosa*.—*T. R.* 1, *Sedum album*; 2, *Sedum lydium*; 3, *Sedum carneum variegatum*; 4, *Veronica incana*; 5, *Lycopodium clavatum*.—*Fechney.* 1, *Nephrrolepis tuberosa*; 2, *Asplenium labellifolium*; 3, *Adiantum cuneatum* probably, but very imperfect; 4, *Pteris tremula*; 5, *Selaginella pubescens*; 6, *Platyloma rotundifolium*.—*Southampton.* 1, *Pitramia vulgaris*; 2, *Sedum Sieboldii variegatum*; 3, *Plumbago Larpenste*; 4, *Veronica spicata variegata*; 5, *Pteris sanguisorba*; 6, *Argemone hispida*.—*L. H.* 1, *Ocoidium obryzatum*; 2, *Oncidium holochrysum*; 3, is curious, but indeterminate. Why do you send such wretched scraps? Do you think it is an easy matter to determine a miserable scrap, crushed and dried before it reaches us?—and do you think that we have nothing else to do? Perhaps our time is as valuable as yours.

POPLAR CUTTINGS: *G. B.* We believe you will succeed in a warm border not too wet.

RABBITS: *H. & Co.* Try Mr. Tillery's plan: well mix a quantity of cow-dung with quicklime and some train-oil, and paint the stem of the trees with the mixture.

THAMNOCALANUS FALCONERI OR ARUNDINARIA FALCATA: *B.* See *Gardener's Chronicle*, June 16, 1877, and numerous notices in our volume for 1876.

TUBEROUS BEGONIAS: *P. G.* Keep them in pots of dry earth, in a place quite safe from damp and frost. The pots might be placed on a dry greenhouse shelf, or in a store-room.

* Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editors would also be obliged by such communications being sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish us to see. *Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editors.*

FOREIGN SUBSCRIBERS sending Post-office Orders are requested to make them payable at the post-office, King Street, Covent Garden, London, and at the same time to inform the Publisher at the office of this Journal.

CATALOGUES RECEIVED.—Messrs. Hooper & Co. (Covent Garden Market, London, W.C.), Catalogue of Bulbs, &c.—Messrs. Edmondson Bros. (10, Dame Street, Dublin), Catalogue of Bulbs, &c.—Auguste Van Geert (Ghent, Belgium), English Edition of General Plant Catalogue.—R. B. Matthews (65 and 67, Victoria Street, Belfast), Descriptive Catalogue of Dutch Flower Roots.—Thomas Meehan (German-town Nurseries, Philadelphia), Wholesale Catalogue of Trees, Shrubs, &c.—Messrs. Daniel Bros. (Norwich), Illustrated Catalogue of Dutch Flower Roots.—W. H. Rogers, 132, High Street, Southampton), Catalogue of Dutch Bulbs, &c.—Messrs. Carter & Co. (237, High Holborn, London, W.C.), Catalogue of Dutch Flower Roots.—Messrs. W. Paul & Son (Waltham Cross, Herts), Catalogue of Roses.

ERRATA.—We are requested to state that the Dahlia "Mr. Seaman," mentioned in our report of the Bishop Auckland show as "a new Northern flower," was sent out by Messrs. R. Edwards & Son in 1875.—In our report of the Seveoaks Show, Miss Don Seale should have been 1st for single epergne, and Mrs. Bolton 2d.

COMMUNICATIONS RECEIVED.—*W. Pontey* (we did not consider it to be better than others now in cultivation).—*C. Ford.*—*W. Pain.*—*D. T. D.*—*N. S.*—*W. D.*—*M.*—*A. G.*—*H. H.*—*Rchb. f.*—Messrs. DIED, on September 18, aged 57, Mr. JOHN MORSE, of The Nurseries, Dursley, Gloucestershire.

Markets.

COVENT GARDEN, September 20.

Business has been steady during the last few days, and in all home-grown produce prices remain the same. Heavy consignments of Kent Cobs have reached us, and a slight reduction has been made to effect clearances. *James Webber, Wholesale Apple Market.*

SEEDS.

LONDON: Sept. 19.—There is more business now doing in red Clovers. Offers of new seed are to hand from both the north and south of France, and also from Germany. Further advices from across the Atlantic describe the prospects of the American crop as good; similar accounts are also received from Canada. With the promise, therefore, of an abundant supply from various sources, currencies will, it is hoped, remain at a moderate level. Alsike, as the result of recent speculative dealings, has crept up to a good figure. White Clovers are steady, but present quotations cannot be pronounced high. For Trefoil, holders manifest great firmness; the undoubted shortness of this season's crop naturally enhances values. There is still, for the time of year, a fair sale for Trifolium on former terms. In neither Mustard nor Rape seed is there this week any material alteration. Fine samples of new Essex white Mustard have been realising long prices; a good supply, it is said, may be expected from Cambridgeshire. In grass seeds there have lately been a few transactions, at slightly enhanced rates. For sowing Rye the sale is slow. Winter Tares, however, move off briskly, at fully the late advance; the yield nowhere appears satisfactory. For bird seeds we have a moderate inquiry, at last week's prices. Blue Peas are rather dearer. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.*

CORN.

Trade at Mark Lane on Monday was decidedly firm, and there was a steady demand for all good produce. The supply of new English Wheat was small, while the prices realised ranged up to 65s. per quarter. Feeding Barley was 6d. to 1s. dearer than on Monday se'night; malting qualities were fully as dear. Malt was steady on former terms. Oats were quite 6d. per quarter higher, while there was a like improvement in the value of Maize. Beans and Peas were much the same in price. Flour was sold at rather better prices in some instances without leading to a general advance being reported.—On Thursday the supply of English Wheat on sale was moderate and condition poor. Choice qualities were in steady request, at full prices, but for inferior produce the trade was slow. Good and fine dry fresh Wheat was held at fully late rates, and the trade for feeding descriptions was decidedly firm. Oats, Beans, and Peas were in fair average request, and no material change took place in their value. Flour was in moderate demand at full prices.—Average prices of corn for the week ending Sept. 15:—Wheat, 59s.; Barley, 40s. 1d.; Oats, 27s. 2d. For the corresponding period last year:—Wheat, 46s. 11d.; Barley, 37s. 7d.; Oats, 26s. 3d.

CATTLE.

At Copenhagen Fields on Monday there was a large increase in the supply of beasts and a heavy trade, consequently prices were lower. The number of sheep were about the same as on Monday se'night, but the demand was decreased, and prices were lower on the average, with a slow trade. Choice calves were scarce, and made fully late rates. Quotations:—Beasts, 4s. 4d. to 5s., and 5s. 4d. to 5s. 10d.; calves, 5s. to 6s. 4d.; sheep, 5s. 4d. to 5s. 10d., and 6s. 4d. to 6s. 10d.; pigs, 4s. to 5s. 4d.—On Thursday, notwithstanding very short supplies, trade was quiet. Both beasts and sheep sold slowly, and the prices realised were about on a par with those of Monday. Calves were unaltered, and pigs sold at about late rates.

HAY.

The Whitechapel report for Tuesday says that, with a moderate supply, trade was steady, at firmer prices. Quotations:—Prime old Clover, 100s. to 150s.; inferior, 85s. to 95s.; good new, 100s. to 135s.; prime old meadow hay, 90s. to 120s.; inferior, 70s. to 85s.; good new, 80s. to 100s.; straw, 44s. to 57s. per load.—On Thursday a good supply of fodder was on sale. With a fair trade prices were as on Tuesday.—Cumberland Market quotations:—Superior meadow hay, 116s. to 126s.; inferior, 84s. to 96s.; superior Clover, 138s. to 147s.; inferior, 110s. to 126s.; and straw, 54s. to 58s. per load.

POTATOS.

The Borough and Spitalfields markets reports state that with moderate supplies trade continues steady, the following being the current quotations:—Kent Regents, 95s. to 120s. per ton; Essex ditto, 85s. to 110s.; Victorias, 100s. to 130s.; kidneys, 80s. to 120s.; Early Rose, 90s. to 115s.; rocks, 80s. to 90s.—The imports into London continue upon a very limited scale. During the past week 962 bags were received from Hamburg, 195 Antwerp, 183 Rouen, and 152 from Harlingen.

COALS.

The following prices were current at market on Wednesday:—Bebside West Hartley, 17s. 3d.; East Wylam, 17s.; Hastings Hartley, 17s. 3d.; Walls End—Haswell, 20s. 6d.; Hetton, 20s. 6d.; Hawthorns, 18s. 3d.; Lambton, 20s.; Original Hartlepool, 20s. 6d.; South Hetton, 20s. 6d.; East Hartlepool, 20s. 3d.; South Hartlepool, 18s. 6d.; Tees, 20s. 3d.

Harrison's Musk.
 VALUABLE BEDDING PLANT.
H. CANNELL begs to assure the Public generally that the above now creates quite a sensation in Covent Garden—in fact, there is quite a mania for it, probably a more saleable and profitable was never sent out. H. C. will send two plants, post-free, for 1s., 20s. per 100.

Seedlings.
H. CANNELL begs to announce that he has many thousands of PRIMULAS, CALCEOLARIAS, and CINCERARIAS, at 1s. 6d. per dozen. They are now just ready for potting off. Those established in small pots, 1s. per dozen extra. All of them are of James' First Prize Exhibition varieties. Special prices for large quantities.

Strawberries all the Year Round.
 GARIBALDI (true).

H. CANNELL begs to inform the Public that he has many thousands of the above invaluable variety, established in small 60s, just ready for shifting, 15s. per 100; Plants from Ground, 6s. per 100. From the fact of his being situated in the midst of hundreds of acres of the Kentish Fruit Plantations H. C. is enabled to offer really all the best and most approved kinds of Strawberries in cultivation. A half-penny card will bring you full and valuable particulars.

ARREST YOUR PURCHASES of all other Cake until you have read the "Book of Testimonials" from users of this Cake. Sent post-free by the Agent for the County, or by the Makers.
 Mills, Shad Thames, London, S.E.

GISHURST COMPOUND.—Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s. 3s., and 10s. 6d. Wholesale by **PRICE'S PATENT CANDLE COMPANY** Limited.

AMIES' CHEMICAL MANURE.
Used by the Royal Horticultural and Botanic Societies.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES,
FRUITS, GRASS, VINES.
 PREPARED IN A FINE, DRY, INODOROUS POWDER.
Prices, £12 per Ton; 15s. per Cwt.; and in Canisters, 1s., 2s. and 4s. each.

Trial Orders of the Manure are invited, to be used in comparison with other Manures.
 Write for Further Particulars to
AMIES' CHEMICAL MANURE CO. (LIMITED),
 79, MARK LANE, LONDON, E.C.

THE EUREKA POST BOX.—

HEREMAN AND MORTON,
HORTICULTURAL ENGINEERS,
2, GLOUCESTER STREET, REGENT'S PARK,
LONDON, N.W.

For Sale, a
STEVENS' IMPROVED TRENTHAM
WROUGHT IRON HORTICULTURAL BOILER,
6 feet long by 3 feet diameter, fitted with Inlet and Two Outlet Pipes, Fire-door and Grate complete. For price and particulars apply to
HILL AND SMITH, Brierley Hill Ironworks, Dudley.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 "	18 "	300	7 0 0
20 "	18 "	24 "	400	8 0 0
20 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	30 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
24 "	24 "	42 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Balham Hill, S.W., May 29, 1873.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS of HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.
When ordering Boilers please refer to the above advertisement.

STEVENS' TRENTHAM GREENHOUSE BOILER,

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved.

Copy of a Testimonial.

"Messrs. SILVESTER, Royal Exotic Nursery, King's Road, Chelsea, S.W.—Aug. 8, 1877.

"GENTLEMEN,—In reply to your enquiry as to our opinion of your Stevens' Trentham Boilers, we do not hesitate to pronounce them to be *by far the best* Boilers we have ever used. Our establishment is a very large one, and we have tested most of the various descriptions of Boilers which have been brought out from time to time. We originally commenced with one Trentham Boiler, and we have now *thirteen* of various sizes at work.

"For certainty of action, economy in fuel, and freedom from breakdown, we have never had a Boiler at all equal to the Stevens' Riveted Trentham Boilers supplied by you, and we have never felt so little anxiety in connection with our hot-houses during the cold winter months as we do now.

"We are not in the habit of giving testimonials, but we think this may fairly be an exception to our rule, as the matter is one of such importance to the Gardening Public generally, and our experience has led us to form a very decided opinion.

"We are, Gentlemen, yours faithfully,
"JAMES VEITCH and SONS."

For Illustrations, with full particulars, apply to the Sole Makers,

F. & J. SILVESTER,

HOT-WATER ENGINEERS, &c., &c.,
Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

AN EXTRAORDINARY BOILER.—

During the Great Boiler Contest at Birmingham, in 1872, all Boilers were severely tested to prove their respective merits. One test was, "How long can each Boiler go without Night Attention?" However, one Boiler proved this to a surprising degree, as after being shut up for twelve hours (from 9 P.M. to 9 A.M.), it still retained its heat in 1000 feet of 4-inch pipes, and yet had more than 1 bushel of fire drawn from its furnace in the morning—equal, in point of fact, to seventeen hours of continuous firing. What a boon to Gardeners. This was THE CHAMPION, Deards' Patent Close-Coil Boiler, for Drawings and Prices of which send two stamps to

Messrs. DEARDS, Boiler Works, Harlow, who now have their Boilers at work in every county of England except three. Amateurs will also find THE WONDER, a smaller kind of Boiler, equally as satisfactory, and certainly "the best thing" out. Awarded five First Prize Silver Medals.

AGRICULTURAL LOCOMOTIVES,

STEAM PLOUGHING MACHINERY,
ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES,
STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,

AVELING & PORTER,

ROCHESTER, KENT; 77, CANNON ST., LONDON, E.C.; and 9, AVENUE MONTAIGNE, PARIS.

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their 10-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power, with a consumption of three and one-fifth pounds of coal per horse-power per hour.

GREENHOUSE BOILERS.—

Two for Sale. For particulars apply to GARDENER, 31, Upper Hamilton Terrace, St. John's Wood, N.W.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK

VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877. "The Kyles, Alderly Edge, Manchester.—Messrs. Hill & Smith.—Sir,—For some 20 years I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted.

—Yours respectfully, ALFRED LOVE, J.P.

Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 113, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

CARSONS' PAINT,

PATRONISED BY THE QUEEN, H.R.H. THE PRINCE OF WALES, H.R.H. THE DUKE OF EDINBURGH, The British, Indian and Colonial Governments, 10,000 of the Nobility, Gentry, and Clergy, Railway and Canal Companies, Collieries, Ironmasters, &c., &c., Is extensively used for all kinds of

OUTDOOR WORK.

It is especially applicable to WOOD, IRON, BRICK, STONE & COMPO. CAN BE LAID ON BY UNSKILLED LABOUR.

Sold in all Colours. 2 cwt. free to all Stations. Prices, Patterns, and Testimonials Post Free.

The *Midland Counties Herald* always contains large numbers of advertisements relating to Farms, Estates, and Residences for Sale and to be Let.

Garden Fruit Tree Culture.

THE MINIATURE FRUIT GARDEN. Eighteenth Edition. By THOMAS RIVERS, 3s. 6d., post-free, from Messrs. THOMAS RIVERS and SON, Sawbridgeworth, Herts; and Messrs. EDMONDSON BROS., 10, Dame Street, Dublin, Ireland. Sold also by Messrs. LONGMAN AND CO., Paternoster Row, London, E.C.

ADVERTISERS are requested to note that although we do not object to receive Letters to be called for, we cannot undertake to forward them.

PARTNERSHIP.—A Nurseryman, carrying on a successful business within 25 miles of London, is desirous of meeting with a Partner. Failing health causes Advertiser to wish to find a man, or men who in, say, one or two years would be able to take over from him the entire business. Money would be required, but every facility be afforded provided substantial guarantees were given. The fullest references given and required.—Address, by letter, giving outline of means and position, NURSERYMAN, Messrs. Norris, Allens & Carter, Solicitors, 20, Bedford Row, London, W.C.

WANTED, where two Under Gardeners are kept, a GARDENER, not under 30 years of age; must understand the Management of both Flower and Kitchen Gardens, Grapes, Melons, and Cucumbers.—JOHN WRIGHT, Esq., Hatfield Priory, Chelmsford, Essex. (Railway Station, Witham.)

WANTED, at Herne Hill, S.E., a married Man, as SINGLE-HANDED GARDENER; must understand Vines, Wall Fruit, and Kitchen Garden, and make himself useful looking after Stock, Wife, Poultry and Dairy. Rent-free. No children; single man not objected to.—State wages, with reference, or call on Dr. SANDFORD, 76, Jermy Street, St. James, S.W.

WANTED, an energetic Man as GARDENER, one who is accustomed to Grow for Market, to take Charge of Small Garden and several Glass-houses, to Grow Plants and Cucumbers, &c., for Market. Married, with no family preferred. Liberal wages given.—Apply, by letter to ALPHA, Rochester, Kent.

WANTED, where two only are kept, a SECOND GARDENER, age about 24; single; must be strong, active, and have had considerable experience under Glass and Kitchen Garden. Wages, 24s., advancing no lodging.—Apply, personally, or by letter, with full particulars, to F. B., 42, Lee Terrace, Blackheath, S.E.

WANTED, an INDOOR FOREMAN; one who has a good knowledge of Plants, good Salesman, experienced in Growing Plants and Cut Flowers on a large scale. Permanent situation to an energetic and competent man. Wages, per week and house. No references wrote to previous to first writing to the applicant.—W. T., Messrs. Hurst & Son, Seed Merchants, 6, Leadenhall Street, E.C.

WANTED, One or Two good JOBBING HANDS.—Apply to J. DALBY, High Street, Sutton, Surrey.

WANTED, for Forest Tree Department, an active Young MAN. State age, experience, and wages required.—JAMES DICKSON AND SONS, Newton Nurseries, Chester.

WANTED, TWO good NURSERY HANDS.—W. AND J. BROWN, Stamford.

WANTED, during the busy season, as SALESMAN and to execute Orders in a large Nursery rapidly extending both its wholesale and retail connections, a first-class practical Man, who has had experience in all practical details of the business. A permanent situation would be offered to a suitable person, who must have had experience in the Management of Men.—Apply, in the first instance, by letter, giving references, age, &c., to HORTUS, Tavistock Hotel, Covent Garden, London, W.C.

To the Seed Trade.

WANTED, a SHOPMAN, for a Provincial Business.—Apply, by letter only, stating age, terms, experience, references, &c., to P. C., Minier & Co., 60, Strand, London, W.C.

WANTED, a NURSERY CLERK and CORRESPONDENT; must have a good general knowledge of Plants, and be qualified to Travel occasionally if required.—Apply, by letter only, stating salary expected and other particulars, addressed to The Lawson Seed and Nursery Company (Limited), Edinburgh.

Seed Trade.

WANTED, IMMEDIATELY, a thoroughly efficient and smart COUNTER-HAND; one who has been regularly trained to the business in a large, well-regulated establishment.—Address, stating age, references, salary expected, and when present engagement expires, M. M., *Gardener's Chronicle* Office, W.C.

WANT PLACES.

E. G. HENDERSON AND SON have many excellent GARDENERS with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

E. P. DIXON can at present recommend several excellent GARDENERS and will be pleased to answer any enquiries from Ladies and Gentlemen requiring such.—The Yorkshire Seed Establishment, Hull.

Head Gardeners.

JOHN LAING AND CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for First-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stanstead Park and Rutland Park Nurseries, Forest Hill, Lodon, S.E.

GARDENER (HEAD).—Age 30, married; understands Grapes, Melons, Cucumbers, Stove and Greenhouse Plants, and Flower and Kitchen Gardening. Excellent character.—J. SEWELL, White's Yard, Huntingdon.

GARDENER (HEAD), where two or more are kept.—Age 30; thoroughly practical in all branches of the profession. First-class testimonials as to character and ability.—H. PYBUS, Castle Bolton, near Bedale, Yorkshire.

To Noblemen and Gentlemen.

GARDENER (HEAD).—Age 32, married, 4 young children; thoroughly experienced in all branches of the profession. Can be highly recommended.—C. B., 52, Moffat Road, Thornton Heath, Croydon, Surrey.

GARDENER (HEAD).—Age 32, married, 2 children; thoroughly practical in all branches of the profession. Three and a half years' good character. Please state particulars.—W. G. H., Filsham Cottage, St. Leonards-on-Sea, Sussex.

GARDENER (HEAD).—Middle-aged, no single-handed place accepted. First-class character from last and previous places. Seven years in last situation. Please state wages.—F. CLARKE, Alderbourne, Gerrard's Cross, Bucks.

GARDENER (HEAD).—Age 38, married; thoroughly competent to take the Entire Charge where trust and confidence are required. Leaving through death. Eleven years' good character. Please state wages, &c.—W. ROWE, Histon Hall, Cambridgeshire.

GARDENER (HEAD), where not less than four are kept.—Age 37, married; thoroughly competent in every department of the profession, or any duties connected with a Gentleman's Estate where energy and intelligence are required. Highly recommended by present employer.—A. G., Barham, East Hoathly, Sussex.

GARDENER (HEAD), where a thorough practical Man is wanted, and four or more are kept, and cottage found. Twelve years' experience in some of the best gardens in England. First-class testimonials from previous and present employers.—G. W., Post-office, Farington, Alton, Hants.

GARDENER (HEAD), where three or more are kept.—Age 30, married; Scotch; fourteen years' experience; understands Gardening in all its branches, and could take the Management of a small Estate. Open for engagement about the beginning of November next. First-class references.—T. MCK., The Gardens, Aytou, Bridge of Earn, Perthshire, N.B.

GARDENER (HEAD, WORKING).—Single; twenty years' practical knowledge of the profession in all its branches. Character will bear the strictest investigation.—A. B., 48, Cochrane Street, St. John's Wood, London, N.W.

GARDENER (HEAD, WORKING).—Age 30, single; thoroughly understands Early and Late Forcing, and Flower and Kitchen Gardening. Five years' good character.—G. D., Orchard Street, St. Albans, Herts.

GARDENER (HEAD, WORKING).—Middle-aged; could Superintend a small Farm as well. Wife a first-class Laundress or Dairywoman, or could take Charge of a Gentleman's House. Good testimonials.—GARDENER, 19, Kemp Place, Glen Ogle Road, Edinburgh.

GARDENER (HEAD, WORKING).—Age 31, married; has had eighteen years' experience in good Gardening, including Early and Late Forcing, Vines, Melons, Cucumbers, Stove and Greenhouse Plants, &c.; has a knowledge of Meadow Land and Stock.—G. B., Gardener, Calverton Limes, Stoney Stratford, Bucks.

GARDENER (HEAD, WORKING), where one or more are kept.—Age 27; eleven years' experience in all branches; thoroughly competent and trustworthy. Two years in last situation. Any inquiries respecting character and abilities would be willingly answered by last employer.—J. G., 150, Haverstock Hill, London, N.

GARDENER—To take the Management of a Square. Five years in last place.—A. B., 64, Arlington Road, Camden Town, N.W.

GARDENER in a Gentleman's Place.—Age 22; native of Denmark; eight years' experience.—First-class testimonials.—P., 19, Pond Place, Fulham Road, Brompton, S.W.

GARDENER, where assistance is given.—Young, married; well up in all branches of the profession.—T. MALPAS, Walker Street, Usk, Monmouthshire.

GARDENER.—JOHN COWAN, The Vineyard, Garston, near Liverpool, would be glad to recommend to any Nobleman or Gentleman requiring a first-class Gardener a Man in the prime of life, who thoroughly understands the profession in all its branches, having had many years' experience in some of the best places in England and Scotland.

GARDENER (SECOND), or JOURNEYMAN, in a Gentleman's Establishment.—Age 23; nine years' experience in all branches of the profession. Good references.—W. T., Royal Horticultural Society Gardens, South Kensington, S.W.

GARDENER (UNDER).—Age 20; five years' experience. Good references.—HENRY COX, North-end, Henley-on-Thames, Oxon.

GARDENER (UNDER).—Age 28, single. Good character.—J. R., Post-office, West Smethwick, Birmingham.

GARDENER (UNDER).—Age 28, married when suited; seven years' practical experience in all branches. Can be highly recommended. Please state wages.—C. S., The Gardens, Aldershot Park, Aldershot, Hants.

GARDENER (UNDER), or good JOURNEYMAN.—Age 23; nine years' experience. Good character from present and previous places.—Apply, with particulars, to R. ABBEY, The Gardens, Seaham Hall, Sunderland, Durham.

FOREMAN, in a Gentleman's Garden.—Young. Can have two years' excellent character from his present place.—E. M., Post-office, Scole.

FOREMAN, in a good Establishment, age 24.—J. ARNOLD can with confidence recommend a young Man as above to any Gentleman or Gardener requiring the services of a good man. Please state wages, &c.—The Gardens, Drakelowe Hall, Burton-on-Trent.

FOREMAN, or SECOND, in a Gentleman's Establishment.—Age 23. Eight years' experience in good situations. Good testimonials.—W. STREET, Scawby, Brigg.

FOREMAN, or SECOND, in a Gentleman's Garden.—Age 24; has a good general knowledge of the profession. Three years' good character.—K., 1, Clifton Terrace, Nightingale Road, Wood Green, N.

FOREMAN, or SECOND, in a good Establishment.—Age 24, single; well up in the general routine of Gardening. A good tenor voice, and would be willing to join a parish choir, having been in one ten years. Three years' good character.—W. C., next to Great Northern Railway Station, Windmill Hill, Enfield.

To Nurserymen.

MANAGER, or WORKING FOREMAN.—A. WARNE is desirous of a re-engagement where plants are grown in large quantities, either retail or wholesale. He is practically a thorough good Grower of Stove and Soft-wooded Plants, also well understands Forcing of Bulbous and other Plants. Formerly employed by Mr. I. Reeves, Acton, Middlesex; Messrs. Carter & Co., Forest Hill; Messrs. Filton & Sons, Birmingham; and his present employer is Mr. T. Gilbert, Springfield Nursery, Hastings, by whom any enquiries will be answered.—A. WARNE, 1, Ashburnham Road, Clyde Vale, Hastings.

PROPAGATOR, and FOREMAN (INDOOR), in a good Market Nursery.—For particulars apply to F. S., 40, New Street, Altringham, Cheshire.

PROPAGATOR (INDOOR), where Roses, Conifers, Clematis, Rhododendrons, and Soft-wooded Plants are required in large quantities.—Age 22. Six years' excellent character.—Address, stating wages, G. ROY, Messrs. Charles Lee & Lon, Wood Lane Nursery, Isleworth, Middlesex, W.

PROPAGATOR (UNDER), or as ASSISTANT.—Good experience and references.—J. J., 10, Essenden Terrace, Plumstead Road, Kent, S.E.

JOURNEYMAN, in the Houses.—Age 23; has had good practical experience in large Establishments. Good recommendations.—A. B., Brooklands Cottage, near Abergavenny, Monmouthshire.

JOURNEYMAN, in the Houses.—Age 21. Eighteen months under the Foreman in last situation. Good character.—GARDENER, J. Derham, Esq., Sneyd Park, Bristol.

To Gardeners.

IMPROVER (a Youth), in a Gentleman's Garden, under a Foreman.—For particulars apply to The GARDENER, Acton Burnell, near Shrewsbury.

IMPROVER, in a Gentleman's Garden.—Age 20; has a fair knowledge of Outdoor Work, but wishes to improve in the General Routine of Gardening. Good character.—A. W., 3, Park Road, Penge Park, S.E.

Sold everywhere, and Wholesale to R. ELLIS AND SON, Ruthin, North Wales, London Agents: W. BEST AND SONS, Henrietta Street, Cavendish Square.

HOLLOWAY'S PILLS.—The blood being the very essence of health and life it is most essential that it should be thoroughly purified before the depressing influences of winter display themselves. These Pills will accomplish this purification in a safe and satisfactory manner, and put the circulation in that desirable condition, which alone can rightly form flesh, bone, muscle, nerve, and skin. Capricious appetites, weak digestions, torpid livers, and irregular bowels are corrected by this potent medicine, which may be truly said to induce "a sane mind in a sound body." Holloway's Pills possess the remarkable property of cleansing without weakening. While purifying they are strengthening and adding to those enjoyments of life which health and vigour can alone bestow.

Edmonton.

TO BE SOLD, a small NURSERY, with Houses and Stock. Apply to Mr. L. R. THOMPSON, 2, Prospect Cottages, Snell's Park, Edmonton.

MONRO'S NURSERY, POTTERS BAR,

TO FLORISTS, FRUIT GROWERS, AND MARKET GARDENERS.

TO BE LET OR SOLD.

TO BE LET for any number of years that may be agreed upon, or J. MONRO will SELL the FREEHOLD; and three-fourths of the purchase Money may remain on mortgage at five per cent. per annum.

This very extensive establishment (14 miles from London on the Great Northern Railway and within 1 mile from Potters Bar station) offers a most excellent opportunity to a practical and energetic person either as a Tenant or Purchaser.

The property is capable of being developed to such an extent as might make it a matter for favourable consideration by a Company.

In the event of the above neither being Let or Sold on the conditions as stated, J. M. will be glad to treat with a thoroughly competent person as PARTNER, who would take the Management of the Glass Department.

For full particulars, apply to Mr. JOHN MONRO, Potters Bar, N., or to Mr. GEORGE MONRO, Fruit Salesman, Covent Garden Market, London, W.C.

THE

IMPROVEMENT OF LANDED ESTATES, By DRAINAGE, ENCLOSING, CLEARING, THE ERECTION OF FARM BUILDINGS and COTTAGES, WATER SUPPLY, &c.

The Land Loan and Enfranchisement Co.

(Incorporated by Special Act of Parliament.)

ADVANCES MONEY.

1st.—To the OWNERS of SETTLED and OTHER ESTATES, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing and General Improvement of Landed Property in any part of the United Kingdom.

2d.—To the OWNERS of SETTLED ESTATES in ENGLAND for the Erection or Completion of Mansions, Stables, and Outbuildings, and for the Construction or Erection of Reservoirs, and other Works of a permanent nature, to supply Water for the use of the Estate, or for any other purpose.

3d.—To LANDOWNERS generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.

4th.—To INCUMBENTS, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.

5th.—To COPYHOLDERS, for the Enfranchisement of Copyhold Lands.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years.

No investigation of the Landowner's Title is necessary. Forms of application, and all further particulars may be obtained of

Messrs. RAWLENCE and SQUAREY, 22, Great George Street, Westminster, S.W., and Salisbury; of Messrs. ASHURST, MORRIS, CRISP, and CO., 6, Old Jewry, London, E.C.; of Messrs. GILLESPIE and PATERSON, W.S., 81A, George Street, Edinburgh, Agents for the Company in Scotland; and at the Offices of the Company, as below.

T. PAIN, Managing Director.

EDWIN GARROD, Secretary.

Post-free on application.

Hale Farm Nurseries, Tottenham, London.

NEW LATE-KEEPING BLACK GRAPE,

"ALNWICK SEEDLING."—This Grape was exhibited before the Fruit Committee, South Kensington, February 6, 1876, under the name of Clive House Seedling, a name the Committee have since thought fit to alter. The following is the description given by the Fruit Committee:—"It is a seedling between the Black Morocco and an unnamed variety raised at Wortley. The bunch shown was of fair size and well shouldered, and the berries large, oval in form, and jet black in colour, with a thick skin. The flavour was decidedly good, partaking of the rich sparkling flavour of the Black Morocco, but much sweeter. It has kept well till February, and will, no doubt, keep longer and prove a better Grape for general cultivation than the Black Alicante." This has been awarded a First-class Certificate. B. S. W. has much pleasure in offering this fine new Grape, believing it to be a decided acquisition. The stock offered is from the original plant. Early orders are respectfully solicited, as the stock is limited. Price 25s. and 42s. each.

NEW FIG, "HARDY PROLIFIC."—The fruit of this hardy Fig is about the medium size, Pear-shaped, rather tapering towards the stalk. The flesh is very sweet and luscious. It was introduced from France some few years ago, and has proved itself perfectly hardy. It must become a general favourite, as it is a very abundant bearer, either in pots or in a cold house, as well as on an open wall. It also ripens earlier than any other variety we know of. Price 10s. 6d. each. Extra sized fruiting plants, 25s. each.

B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London, N.

To be Sold Cheap, for Want of Room.

THE FOLLOWING SPECIMENS

and strong plants:—

AMIES' CHEMICAL MANURE.

USED BY THE ROYAL HORTICULTURAL AND BOTANIC SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.

PREPARED IN A FINE, DRY, INODOUROUS POWDER.

Price, £12 per Ton; 15s. per Cwt.; and in Canisters, 1s., 2s. and 4s. each.

Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to AMIES' CHEMICAL MANURE CO. (LIMITED), 79, MARK LANE, LONDON, E.C.

SCOTT'S WASP DESTROYER.

The only preparation made for thoroughly destroying Wasps, large Flies, &c. Sold in bottles, at 1s. 6d., 2s. 6d. and 5s. each. The larger sizes are the cheapest. May be obtained through any Seedsman, or direct from JOHN SCOTT, The Royal Seed Stores, Veovil.

B G L Oils &c.

ARREST YOUR PURCHASES of all other Cake until you have read the "Book of Testimonials" from users of this cake. Sent post-free by the Agent for the County, or by the Makers. Mills, Shad Thames, London, S.E.

THE QUEEN'S SEEDSMEN, READING.

SATURDAY, SEPTEMBER 29, 1877.

**LESSONS OF THE POTATO
DISEASE.**

THE near approach of the International Potato Exhibition, and with it the customary gathering of the leading cultivators of the Potato, presents a fitting opportunity to consider how far we have, as a nation of cultivators of this most valuable vegetable, profited by the sharp and severe lessons the dread disease that affects the tuber have set us, and whether an annual display of the best samples of Potato probably to be found in the kingdom serves in any material way "to promote the best methods of culture, as well as the introduction and diffusion of new or improved varieties."

It may be accepted at the outset as an undoubted truism that no kind of Potato is impregnable to the attacks of the disease. The foolish and preposterous claims made on behalf of one or two certain kinds were ruthlessly demolished a few years since by the remarkable test instituted by the Council of the Royal Agricultural Society, and proof of the most positive kind was afforded that no variety of Potato possesses any special immunity from the effects of its dread enemy, the *Peronospora infestans*. The occasional freedom from disease which some sorts have enjoyed led to the inception of the boast that these were disease-proof. Another partial immunity this year of a few kinds will doubtless lead to similar boastings. It is, however, well to say at once, that no season passes, let the disease be ever so prevalent, but some sorts are worse and others less affected. There is, indeed, little to guide us in this matter that can be put to practical use, but so far as it can be, we propose to do so in this short paper.

During the present year the wide prevalence of the Potato disease has read us another severe lesson as to the value or otherwise of the prevailing modes of Potato culture, and we have to confess that we are either unable or unwilling to learn anything thereby. In a few cases men really desirous of securing clean, healthy crops of tubers try this or that method, not always on a systematic basis, but rather as their own lights or crotchets lead them, and perhaps partially succeed. Still, the inevitable result is disease more or less, and thus no specific gain to our present stock of useful knowledge has resulted. It is hardly worth speculating as to how the disease first became a denizen in our midst—we know that it came upon us more than thirty years since like the shock of an earthquake, that from the eventful year of 1844 down to the present time it has appeared here with more or less virulence, its efforts for ill being at times held in check by a warm, dry season. But in spite of all the science lavished in inquiry, in spite of the experience of so many years, and the consequent closer acquaintance with the operation of the disease that has resulted, we are still its apparently helpless victims, still unable to check its inroads upon our crops, or offer to it any tangible opposition.

Just as—to use a homely phrase—"It's no use crying over spilt milk," so also it is of no use to mourn over our past losses. What we ought to set ourselves to do is to see how far the past has served to aid us in obtaining some immunity in the future. It will, perchance, be looked upon as a startling assertion, and perhaps

as one indicative of questionable sanity, when we propound the belief that the conversion of the Potato from a mere garden luxury into an article of general consumption, has had something to do with the widespread destructiveness of the disease. Looked at superficially, it may be said that this is a self-evident assertion, as the greater the area under cultivation the greater the destruction wrought in the crops. We, however, mean something wholly dissimilar from this, and say more plainly that it is the element of size in the Potato—that is, "bulk"—both in crop and in tuber, that has so much to answer for. Growers of roots hesitate to accept the statement of the chemist that the larger the bulbs or tubers, the greater the proportion of water, the less of nutritive matter; in fact, the larger the roots the less do they become healthy and health-giving compounds, and the nearer do they approach to diseased bodies, to which disease easily assimilates.

It is a well known fact in physiology that the human frame presents elements of disease or direct tendency thereto in proportion to its fatty development, and it is a notorious fact that the bloated pampered frames of brewers' men, publicans, gentlemen's servants, &c., offer to the medical faculty the worst possible subjects when affected by disease. Just so it may be with the Potato, and indeed is. Wherever high culture, so called, allied to rich soil and an abundance of manures, has promoted a rank growth in the haulm, and large tubercous development, there is the disease the worst, the most virulent, and invariably almost wholly deadly.

This presents a somewhat extreme, but by no means uncommon, form of culture, and growers who have seen the same results follow their labours for twenty years, with occasional exceptions, still follow the same foolish routine, infatuated in the belief that "this year" at least their crops will escape. Next planting time they will have forgotten all that they are now being taught. Ordinary cultivation is that which prevails in our market gardens and large Potato fields in all parts of the kingdom. This is applied for the production of crops for general consumption, and to make it a paying business the tubers must be large and plentiful. Now and then, favoured by the season, the crop is fairly clean and healthy, and then a good profit results, but as a rule there is partial failure, that is, from one-third to two-thirds of the produce is diseased, and then the outcry is great and the loss very heavy; indeed, it may perhaps be safely asserted, taking the average of the past ten years, that growers have been heavy losers by the cultivation of the Potato. It is difficult to reason with consumers who will have their Potatoes at all costs. It is as difficult to reason with growers who are infatuated in the belief that clean healthy crops under the present mode of cultivation will come some day. It is, alas! only too probable that nothing but radical and complete change in our modes of Potato culture and taste will ever enable us to combat effectively with our enemy the disease.

We must determine to forego our love for big tubers, we must find other substitutes for the public taste, we must rather starve the Potato than grow it, and thus by its very meagreness, its leanness and the lack of predisposition to disease consequent thereupon, eventually hope to starve the *Peronospora* out of existence. Our friends of the International Potato Exhibition, in their love and admiration for large samples, will doubtless stand agast at such a doctrine, and carefully wipe from their reputations the charge or reflection that in favouring through their prizes and their judgments the largest tubers they are, therefore, aiding the development of the disease. The possibility of such being the case, however, admits of serious reflection, and in rejoicing

over their success and the remarkable rise of their prize samples, it will hardly tend to self-congratulation if their minds should at times wander towards the thought that after all they are only promoting the production of skins full of moisture, sappy and bloated, ready soil in which the disease will prosper and fatten rather than—as their preface puts it—"best methods of culture and the introduction of improved varieties." Small Potatoes are rarely affected with the disease, it is less destructive in poor soil, it is less destructive in a light, dry, gravelly soil, but is worse in soil that is moist and retentive, or where there is an abundance of rich manures. Small Potatoes, or those grown on poor land that is dry and porous, and where there is no contact with manure, are ever the most mealy and nutritious and best adapted for food. Large Potatoes grown in rich soil or forced into size by an excess of moisture, are all that we have shown them to be, and nothing better. Let us agree to regard Potatoes in the future less as an indispensable article of general consumption, and more as a delicious adjunct to our vegetable produce, to be grown only to secure a clean healthy crop of small tubers, free from all fungus, and full of nutriment.

It has long been one of the pet ideas of certain theorists that the disease has generated from the careless modes of culture in vogue, by which the strength and health of the Potato has been squandered and its constitution destroyed, but these have all held the necessity of liberal growth, big seed, and the production of strong haulm and large tubers. It is in the process and in the conclusion wherein we differ from these. We hold that strong liberal culture is the worst, and that deterioration has resulted, not from poverty of culture, but rather from an excess of richness. It is truly pitiful to note how some writers continue to drone about the sad results that follow from imperfect seed-storing, and that this led to the rapid deterioration of the Potato. If disease fell only upon the produce of such seed there might be sense in the proposition, but inasmuch as it operates with equal destructiveness upon plants raised from seed saved in the most fitting and suitable way, the argument will not hold water. The seedling theory has also been pretty well ventilated, with no better result. Never were more seedling varieties in cultivation than now, and with what result also? These have not saved us from the disease yet. One writer, in his utter distraction, vehemently calls upon the Government to come and aid him and his fellow growers in their misfortune and distress. To him we would reply by paraphrasing a well known proverb—Government only helps those who help themselves. If the Potato cart has got its wheels fast set in a rut, call not upon the Governmental Jupiter for aid, put your and your fellows shoulders to the wheel, and pull it out yourselves, and then your victory over the disease will be complete.

The present season's lessons to be gathered from the disease are just those that have forced themselves upon our minds for many seasons past. We want a new and precocious race of Potatoes that shall be planted late enough to escape frost, and be lifted early enough to escape disease. Of course it will not be enough that these should have sizeable tubers to make them fit to lift. We want varieties that will ripen in ten or twelve weeks, be of good table quality, will produce a fair crop, and, further, will keep well for six months from the time of lifting. With such a breed as this, two crops in the year would be easily practicable, inasmuch as it is an oft-proved fact that the disease is in its worst form from the middle of July till the middle of August, and is seldom very injurious later on. Thus the first crop would be lifted before the disease appeared, and the later crop planted to be lifted in October would not be sufficiently

advanced to be in harm's way. A most valuable section of the Potatoes of the future, however, will be found in the very strong growing kinds that produce large tubers of good quality. It is to this section we made special reference earlier in this paper, as their occasional comparative immunity from disease has led to their being termed disease-resisting. These large coarse-growing kinds are the very sorts to grow on dry, porous, poor land to produce a crop of clean, medium-sized tubers late in the autumn, to furnish the late winter and spring supply. They have one possible danger. A dry summer is apt to produce a check in the growth, and then moisture following will promote super-tuberation, but this form of growth is only occasional, and is not an unmitigated evil. These late robust sorts have a very erect woody haulm that, if not too luxuriant during the period of disease activity, is sometimes capable of coming through that season of danger with no great injury. If grown with manure and the elements of high culture they will go the way of all other sorts, but if grown only in poor dry land in the open field, and thus made to produce stems of a hard fibrous nature it is most probable that a clean healthy crop of medium-sized tubers will follow.

Here, then, lies the most pressing necessity in future Potato culture. Grow first early sorts, and lift ere the disease is rampant. Grow also late robust sorts to lift in the late autumn for a winter supply. Grow all on poor land, free from moisture and manure, remembering that a bushel of small sound tubers is worth more than a thousand bushels of diseased big ones.

New Garden Plants.

SPATHOGLOTTIS PETRI, *n. sp.**

Spathoglottids are very rare plants in our gardens. Spathoglottis Lobbiai has flowered with Sir Trevor Lawrence, at Dorking; Spathoglottis ixioidea just now be in flower with Herr Stadtrath Leichtlin, at Baden-Baden; and this new one just at hand, is a fresh inflorescence sent from the Royal Exotic Nursery of Messrs. Veitch. It has been sent from the Archipelago of the South Sea, by Mr. Peter Veitch, who has likewise sent home such splendid flowers of the Spathoglottis pacifica as I never saw before, although I have had it before from six localities. It is but justice to name the novelty in memory of this gentleman, who may kindly accept the delicacy *cum grano salis*, viz., as a *captatio benevolentia* for having more dried specimens and with exact localities. If they have to be kept secret, we will do so in so many other cases. The plant is in the way of a good terrestrial Bletia or some Phajuses, though it is not so succulent (s. v. v.) as the last. The long peduncle exceeds 2 feet in length. It is green, with long brown sheaths and becomes sordid purplish, or, to accept Dr. Lindley's expression, port-wine colour at the top, where it has finally a very few very short hairs. The inflorescence has eleven flowers, and may become much richer; they stand in a corymbosely arranged raceme, and four flowers are open at once. The bracts are very large, conspicuous, elliptical, with an apiculus excavately glabrous, whitish, with some traces of light purplish nerves, the apicula dark purplish; the beautiful flower-case much of the colour of those of a well coloured Phalaenopsis Schilleriana, and fully as large as those of a very rich panicle (smaller of course than those of a few-flowered inflorescence). The sepals are ligulate acute. The petals are much broader. The trifold lip has ligulate blunt side laciniae, and the middle lacinia is cuneate, dilated into a transverse short broad three-lobed body, the middle lobe very short, nearly acute, the side lobes spreading outside, blunt; it is beautifully purplish, white in the centre, and there is a rhomboid callosity with three furrows and two longitudinal lines of long hairs just standing between the side laciniae, ochre colour. The

* *Spathoglottis Petri*, *n. sp.*—Foliis latis plicatis lanceolatis; pedunculo elongato, distanter vaginato, apice summo minute subvelutino ceterum calvo; racemo densifloro, corymboso; floribus nonnullis synanthiis; bracteis ovatis apiculatis excavatis calvis deciduis ovarii pedicellatis multo longioribus velutinis; sepalis ligulatis acutis; petalis ellipticis acutis multo latioribus; labello trifido, lacinis lateralibus ligulatis obtusis, lacinia antica cuneata transverso dilatata in laminam brevissimam latam ligulato trilobam lateribus extus obtusis, medio antica acutum; callo interlaciniis lateralibus rhombo trisulcato, lineis villosis longitudinalibus latiusculis geminis, villis ante callum paucis, post callum ante columnam pedem abruptum biseriatis; columna arcuata.—Flores late lilacini. Labellum purpureum, disco albidum, callo ochroleuco, maculis purpureis parvulis appositis.—Ex insulis australisicis misit Petrus Veitch. *H. G. Rehb. f.*

column is arched and light purplish outside, white inside. Spathoglottis Paulowna (also called Bletia Paulowna by a very great mistake) has much smaller flowers and the lip is exceedingly distinct, the most by the simply cuneate ligulate middle lacinia. I am lucky to know it from the type, as it cannot be recognised from the erroneous descriptions. Spathoglottis Viellardi, from New Caledonia, stands very near it, but it has a very different callus and standing much nearer the base of the anterior lacinia. The base of our new plant is plaited, broad, lanceolate. The flowers of the Spathoglottids with even lips are cut much like those of certain Phalaenopsis. The grand Spathoglottis aurea, never seen alive in Europe, has them so much like those of a Phalaenopsis Lüddemanniana and the precious violacea and sumatrana (zebrina) that I hid every Orchidist of the United Kingdom, including the most skillful ones, would judge a single flower of it that of a Phalaenopsis of the group alluded to. *H. G. Rehb. f.*

PHALAENOPSIS STOBARTIANA, *n. sp.**

A curious plant in the way of *P. amethystina*, with very uncommon colours for a Phalaenopsis. Sepals and tepals of a beautiful apple-green colour, ultimately yellowish green. Lip with the lateral partitions white with yellow and amethyst coloured, the middle lobe totally amethyst coloured. This bright amethyst colour finally changes into a nearly cinnamon red. The base of the white column is also amethyst coloured. I had a branch or top of inflorescence with eight flowers, a little smaller than those of *P. equestris* (rosea). That is all I know. Perhaps I may learn more one day. It is dedicated to its possessor, Mr. William C. Stobart, Etherley Lodge, Darlington, and it was grown by Mr. L. Hartley. *H. G. Rehb. f.*

ONCIDIUM HOLOCHRYSUM, *Rehb. f.*

It is a bad thing for an Orchid to be born as an Oncidium, for the majority of amateurs get nervous at hearing the name alone. Some species begin to be better regarded, and we may venture to recommend this one. It is rather unlike in the genus by having grand dense nodding racemes, like some good fox-brush *Aerides*, consisting of beautiful yellow flowers, as large as those of *Oncidium amplatum*. The callus of the lip is very distinct, forming one lobed blade. The wings of the small column are linear. The species appears to be very difficult to grow. I saw it first in 1862 at Mr. Borsig's garden, under the able management of Mr. Gaerd, now Herr Garten-Inspector Gaerd, of Moabot, whose health is much superior to that of his little *Oncidium*. I had not the least idea of the beauty of the plant till Messrs. Backhouse, of York, sent me Dr. Krause's specimen from Ecuador, and nearly at the same time Mr. Linden favoured me with some vestiges dried by Mr. Wallis at the same place, sent in a letter. It had, however, been found before by Mr. William Lobb in Ecuador. So far as my knowledge goes it had only flowered afterwards at Mr. Linden's establishment, who sent me fresh flowers. I obtained recently a single very large flower from the garden of Mr. William C. Stobart, Etherley Lodge, Darlington, grown by Mr. L. Hartley, sent by Messrs. the Editors of the *Gardeners' Chronicle*.

I am sorry to say I have ascertained the plant was known to Dr. Lindley. It is his *Oncidium onustum*, Lindl. (Folia, No. 35), stated to have sword-like ancipitous leaves, apparently white flowers, and to come from Panama and Western Columbia (Cumio, 1208). Since it stands in a group, where nobody can search (its leaves being sometimes folded together, but flat), I am not very clear whether I may cancel my name, as it would have been a fault to name it correctly. I have ascertained by looking to the type that the description of the leaf is wrong, the indicated colour of flowers is decidedly erroneous, and as to the origin a mistake may be suspected. *H. G. Rehb. f.*

PEZIZA COCHLEATA.

It is always a far greater pleasure to the botanist to clear up some old and doubtful point, than it is to discover a new species. We have now such an opportunity, in consequence of the reception of a very curious fungus from Professor Dyer. It forms a complicated cinnamon-brown mass, simulating *Tremella foliacea* so completely, and so exactly agreeing with Bulliard's figure, tab. 499, fig. vi., x y, that at first we concluded that it must be that species, and on a hasty glance we should have committed a serious error in so determining it. It is, however, always well with fungi to have recourse to the microscope; and

* *Phalaenopsis Stobartiana*, *H. G. Rehb.*—Radicebus, foliis et inflorescentia ignotis (racemi parte ?) plurifloro; sepalis tepalisque cuneato-oblongis acutis; labellorū partito; partitionibus lateralibus ligulatis retusiusculis; callo utrinque ante basin; anstula in disco antico; lacinia media obovata medio carinata; callo obcordato et callo anteposito bicuspidato inter partitiones laterales. *H. G. Rehb. f.*

this at once showed that we had a *Peziza* before us; and, anomalous as it seemed, that it was a state of *Peziza cochleata*. We fortunately possessed very characteristic specimens of the brown form, gathered some years since at Lea, in Lincolnshire; and also an authentic specimen of the pale variety from Fries, as also abundant samples gathered by Mr. J. Henderson, at Milton, in Northamptonshire, in 1842. In all we found the paraphyses curved at the tips, as represented by Cooke in *Peziza leporina*, and not simply clavate, as in his figure of *P. cochleatus*. It is, however, quite certain that he had not the true species, as the cap is not turned in after the fashion of an ear, as in the true species, and both Montagne's and Greville's specimens might be badly determined. On turning to Fries' account of the *Peziza*, we find him remarking that he had never seen specimens like those figured by Nees in his *System*, fig. 280, but this is exactly what is before us. Nees von Esenbeck states (p. 262) that the curious malformation he has figured is scarcely to be distinguished from a *Melephora*. It forms, he says, a curled labyrinthiform mass of a dark red cinnamon-brown, the single cups measuring from 2 lines to

ment. The place had been pointed out to me, but so little did it resemble in its surroundings what I had expected to see, that I thought I must have been misinformed. A footpath across the fields from the road brought me in front of a fine old wall some 7 or 8 feet high; in this wall was a small postero-gate, at the side of which hung a bell, such a one as we might imagine to have hung at the gate of a monastery in the olden time; indeed, the whole scene bore the same character. A huge canopy of Ivy overhung the gate, which it almost hid from view; and my pull at the bell caused such a peal as might have been supposed to be necessary to call some prayer-enwrought friar from his devotions; yet, loudly as the reverberation sounded, no one appeared to answer my summons, which repeated over and over again seemed each time more and more a sacrilegious break upon the monastic stillness of the air. With a high wall in front of me, instead of a rugged rock, I began to emulate the ragged ruffian who went round and round the place without any ostensible result, when a distant voice, emanating from a person I could not see, informed me in broad Berkshire that it was no use ringing any more, for Mr. Webb had left at 6 o'clock in the morn-

such was his utter aversion to any kind of intoxicating drink—he had a collection, which was considerable, made of all the alcoholic beverages, and the whole thrown into a deep pit dug for the purpose and buried, over which he had erected the aforementioned monument bearing the inscription, "To the execrated memory of alcohol." Among the features of the garden proper was a gnarled old Apple tree which might from its appearance have begun the world with Methuselab. Throwing out its arms in every direction this patriarch of the grounds bore each season a goodly crop of Apples, and was pointed out to me as a favourite instance of what could be accomplished by unchecked natural growth: Quite as beautiful and no less profitable was a glorious specimen of *Maréchal Niel* Rose, which, allowed perfect freedom of growth, covered an immense space of wall and had made its way into a greenhouse and over an outbuilding, cropping out, in fact, in so many places as to cause one to ask whether the plant confined itself to one county?

Nut trees and Apple trees are *par excellence* the produce at Calcot, and at the time of my visit were in the height of their bearing. Many of them had been raised from seed. The Mulberries were exceptionally fine and rich of hue, and as their roots were in close proximity to the pit in which the wine, &c., was buried, it seemed possible that alcohol might have as inspiriting an effect upon plants as upon human beings. The Fig trees were magnificent, bearing quantities of shining brown or green fruit behind their ample leaves. Luscious Peaches, Plums, and Apricots dotted the walls in no niggardly fashion, and must have proved a source of considerable profit to the proprietor, when we consider the extent of wall upon which they grow—for it is not often possible to find 13 acres, or something thereabout, of fruit garden enclosed within a fine high brick wall, such as environ the Calcot grounds. Spring flowers were a *specialité* with Mr. Webb, and although I never saw them when in bloom I could imagine their profusion from the vast number of the then flowerless plants at my feet.

Vegetable existence at Calcot was exuberant on all sides, and animal life scarcely less so, the whole grounds being guarded from the depredations of birds by some sixty or so cats; from the depredations of man by half-a-dozen magnificent mastiffs, whose very appearance, or whose sonorous bark was sufficient to appal any ordinary thief.

I cannot quit the subject without a reference to the hospitable and characteristic manner in which my host treated me and all his visitors. A table loaded with delicious fruits and cake for all comers, expected or unexpected, was always spread in one of the rooms of the cottage in the grounds, the staunch teetotaler prefacing his invitation to the hermit-like repast with a request that you would go with him and have the finest glass—of water—in England. T. S. J.

FIG 77.—PEZIZA COCHLEATA.

1 inch in diameter. The outer surface consists of beautiful moniliform, globose articulations. The sporidia, which measure the two-thousandth part of an inch in length, have two large nuclei, so as to present a pretty object under the microscope. Our figure (fig. 77) gives the general appearance of the plant, and a magnified representation of the asci with their sporidia and paraphyses. The specimen was sent by G. E. Frere, F.R.S., of Roydon Hall, Diss. He simply states that it was found in the afternoon of August 28 in a shaded pasture under Oak trees. *Helvella crispa* and *Morchella esculenta* are found occasionally near the spot, but he had never seen before anything exactly like this. M. J. B.

RECOLLECTIONS OF CALCOT.

AMONG all the nursery grounds or market gardens I have visited, Calcot stands out most distinctly as being unique in its staple productions, unique in its appearance, and unique in the character of its owner. After a delightful walk along the Bath Road out of Reading one morning in the early autumn some five or six years ago, I made a first attempt to see Calcot, and interview, as our American cousins would say, the genial proprietor; but I was fated to disappoint-

ing, with all his people, to spend the day at the Crystal Palace. I was thus compelled to renounce my purpose for a time; but a few days later I again visited the gardens, meeting Mr. Webb by appointment, and passed some very pleasant hours in his company.

The first thing that strikes the eye is the unlikeness—so to speak—of the place to most gardens, whether nursery or market. In these trimming and pruning are, as a rule, carried out to the fullest extent, and rows upon rows of trees and bushes corresponding in form and size cover acres of ground. At Calcot the pruning knife and scissors were thrown on one side—nut and Apple trees, Roses and Figs, growing in natural luxuriance and most marvellous profusion. Without entering into a long and verbose description of this land of fruit, I will touch only upon some salient and interesting features, which always remain fresh in my memory. One of the most prominent is the vision of the obelisk, which stands a conspicuous object on the left hand side after passing the ivy-clad portal. Many men will do a great deal in defence of their particular opinions, but few would have the courage to make the sacrifice which must ever be associated with the name of the late proprietor of the most celebrated nut gardens in England. When Mr. Webb first took possession of Calcot—

MEEHAN'S NURSERY, GERMAN-TOWN, PENNSYLVANIA, U.S.A.

GERMANTOWN was once a suburb of Philadelphia, but it is now within the city limits. A few days ago I did myself the pleasure of visiting this nursery of about 50 acres, held in fee simple by the proprietor, and stocked with nearly every tree and shrub of this and other countries. Fruit trees are grown by the tens of thousands, and deciduous and evergreen trees in great quantities, of all sizes for ornamental work, lawn, and street planting. The micaceous soil appears to be admirably adapted to the growth of both deciduous trees and evergreens. I have no intention of entailing upon your readers an elaborate detail of such, but beg to give you a few notes on some rarer species and varieties of plants, premising that there is nothing for those to admire who can only see beauties in Butterfly plants and *Codæums*.

EVERGREENS.

A very fine sample of *Pinus contorta*, 2 feet high, dark contour and rigid; *Pinus aristata* or *Balfourii*, of equal size, deep in colour, very fine growth; *Pinus flexilis*, 2 feet high, showing its intention to be silvery in aspect, approaching *Pinus monticola*, but having no relationship to that species.

Abies Engelmanni.—Distinct from all its congeners, having fine, soft, feathery, close-set foliage. This has been propagated by grafts from the original trees on Gray's Peak, Colorado, 14,000 feet above tide-water. There is also a most beautiful plant, nearly 5 feet high,

of a variety of *Abies Menziesii* from Colorado, which in its present state of rich glaucous colour, neat and compact in habit, is certainly the most attractive of all the bardy Pine tribe.

Pinus edulis.—Very handsome specimens of this rather rare Pine.

Pachystema Canbyi.—A very neat, dwarf evergreen, similar to a Myrtle, and reputed to be greener in winter than in summer, and covered with scarlet berries.

Berberis trifoliata.—From Texas, very distinct in foliage, and as hardy as an Oak.

DECIDUOUS TREES AND SHRUBS.

Maclura aurantia aurea (golden-leaved Osage Orange).—The bright green and rich golden foliage form a distinct contrast compared with the sickly golden affairs that we so frequently notice.

Ulmus fulva pendula.—A first-rate form of the weeping Elm.

Cornus florida pendula.—This form of weeping tree has an idea of its own, by being capable of a leading shoot, with all the branches pendulous—a capital formation of a fountain tree. The foliage is large, changing to crimson in autumn, and covered with scarlet fruit or seeds. This is really a Meehan tree, and forms a distinct object on the lawn or landscape.

Liriodendron tulipifera integrifolia.—I have heard of such a plant before, but here it is with very large entire foliage of unequalled shining green, and no mistake.

Quercus undulata, from the Rocky Mountains.—Allow me to call this the Bamboo Oak, from its erect, rapid-growing shoots.

Quercus Engelmanni.—A very rare species, with foliage of every shape and form. Another very remarkable form of the Oak is

Quercus Catesbaei, with its large vertical foliage; an old name, but certainly a new form.

Halesia, new sp. (shall I call it Meehani?), with corrugated foliage, flowers white and cup-shaped, and in form distinct.

Alnus maritima var., with large cones, and the catkins on the end of the young shoot.

Albica pubescens.—Very large foliage, and brilliant crimson fruit at the end of the season.

Oenothera serrulata, from Colorado.—A half-shrubby plant, with yellow flowers, and a companion to *Potentilla fruticosa*.

Salix candida, the true Silver Willow.—The under-surface of the foliage is as white as *Centaurea candida*; the upper surface is whitish; the waving character of the plant makes it a charming object.

HERBACEOUS PLANTS.

Cirsium Pitcherii.—A silvery foliaged plant, excellent for a vase, with its dependent flexile shoots.

Diplopappus linearifolius.—Related to the Aster family, with numerous rosy coloured flowers and Heath-like foliage.

Chilopsis linearis.—Closely related to *Catalpa*, with blue flowers of a *Gloxinia* shape.

Ampelopsis incisa.—A new American Ivy for covering walls and outbuildings, of rapid growth; dark green, trifoliate, thick, waxy foliage: very distinct in all its parts.

Helianthus argyrophyllus.—With large silvery foliage and strong growth.

Clematis ligustifolia.—With clusters of small, white, fragrant flowers, blooming profusely, free in growth; a companion to *Clematis Flammula*.

The vast stock of seedlings of evergreens, *Magnolias*, *Halesias*, *Oaks*, and many others, all for the nursery trade, with thousands of *Liatis pycnostachya*, all in full bloom, the floral portion fully 12 inches long, was a rare sight. Allow me here to thank Mr. T. Meehan for his intelligent company. A few items from memory of the very energetic proprietor may be acceptable to your readers. Mr. Thomas Meehan is a very fruitful scion from your Kew Gardens, and was there with the late Dr. Seemann and others. He came to this country about twenty-nine years ago. His capital was a clear head, a fine, firm physique, and an eye like a diamond; he had neither pride nor fear for an honest life. He was fortunate in entering duty upon a very prominent place, where he was engaged in planting some of the then rare evergreen trees that he can now see 30 to 40 feet high, such as *Abies nobilis*, crowned with cones; *Abies Menziesii*, *Picea pectinata* and *Pinsapo*, &c. From there he went to clear up the Bartram botanic gardens for its new owner, and after two years he went to Springbrook to build new houses and cultivate the *Victoria regia*, at that period a wonder to the floral world. A few years more, and his accumulations being considerable, having always preferred water to wine, he determined to be a nurseryman. You have a part of the sequel, but that is not all—he is the famed editor of the *Gardeners'*

Monthly, the agricultural editor of Forney's *Philadelphia Press*. The Governor of Pennsylvania has lately appointed him botanist to the State Agricultural Society. He is now engaged upon a very large work for a Boston house on American native plants, all to be illustrated in chromo. His library is a treat. I saw a very old work by Salmon, dedicated to Queen Anne, in folio, with 1200 pages of illustrated plants. His parents are now enjoying a ripe old age at St. Clair, Isle of Wight. R. B.

ENGLISH NAMES OF WILD FLOWERS AND PLANTS.*

(Concluded from p. 363.)

The medical beliefs revealed by many names are not less curious than their legendary associations. It was the opinion of the old herbalists or simplers that God had not only provided special plants as a cure for every disease, but had made their curative power evident by stamping them with some resemblance to the malady they were meant to heal; and this faith, known to students of our older botany as the "Doctrine of Signatures," lurks or reveals itself in many an English name. The Lung-wort, spotted with tubercular scars, was a heal for consumption; the Liver-wort, liver-shaped in its green fructification, was a specific for bilious maladies; the scaly pappus of the Scabious for cutaneous eruptions; the throat-like corolla of the Throat-wort, or Canterbury Bell, caused it to be administered for bronchitis; the Saxifrage, cleaving the hard stones with its penetrating fibres, was efficient against calculus; the Scorpion-grass, now known as the Forget-me-Not, whose flower-spike dimly resembles a scorpion's tail, was an antidote to the sting of that or other venomous creatures; the Moon-daisy averted lunacy; the Birth-wort, Kidney-Vetch, Nipple-wort, Spleen-wort, were all appropriated, as their names suggest, according to resemblances, real or fancied. The pretty Toad-flax of our walls and hedges owes its name to a strange mistake. Believed to be the cure for a complaint called hubeos, it received the Latin name *bubonium*. A confusion between *bubo* and *bufo*, which is Latin for a toad, gave birth to its present name; and stories were not long wanting that sick or wounded toads had been seen to eat of it and to recover health.

Similar distortions occur in non-medical names, and it is most curious to notice how soon a story springs up or a belief asserts itself in confirmation of the mistaken identity. The common Fumitory, which we have already noticed, received its name of *fume-terre*, "earth smoke," from its causing the eyes to smart and water when applied to them, as smoke does. The meaning was lost as time went on, and was supplied by the belief that it was produced without seed by smoke or vapour rising from the earth. Buttercup was said to give colour and flavour to butter, as being eaten by cows, when in blossom, the facts being that it is a corruption of *bouton cop*, button-head, and that cows eat the grass all round it, but always, if possible, avoid it. Meadow-sweet is a corruption of Mead-wort, honey-wine plant, a beverage being still extracted from it by cottagers. Bullrush is Pool-rush, as growing in pools, not in mud; Snap-dragon is Snout-dragon, from its shape; Marigold is Marsh-gold; Sweet-William is *willer*, a little eye; Pink is the lower German *Pinksten*, Pentecost, from its flowering at Whitsuntide, the name being transferred first to the colour of the flower, then to a method of working flowers on muslin, called pinking; and so to the sword-stab in a duel, piercing or pinking an adversary as the needle pierced the cambric. Nightshade is *night-scada*, soother, or anodyne; Samphire is St. Pierre, from its love of rocks; Sanicle is St. Nicholas, the restorer of the three murdered children, from its healing powers; Poplar comes from the Indian *Pepul*, whose leaves when varnished and painted closely resemble those of the large Spanish Poplar; Primrose was anciently the Daisy; and is called by Chaucer *Primerole*, from the old French *Primeverole*, the first spring flower; *Primerole* was changed to *Primrolles*, then to *Primrose*, the first Rose of spring; and it was not till the sixteenth century that it attached itself to the familiar flower which now bears its name. Cowslip is more strange still. It was originally "hose-flap," and belonged to the Mullein, whose great flannelly leaf might well be likened to the flap or skirt of a woollen

under-garment. Later on it was transferred to the wild *Primula* of our meadows, and the mistake was stereotyped by the unlucky botanist, who, in ignorance of its origin, gave the name of Oxlip to its pretty congener, the *Primula elatior*. The Jerusalem Artichoke is a Sun-flower, not an Artichoke; but the tubers resemble the Artichoke in flavour. From its Italian name *girasole*, turn to the sun, came Jerusalem; and by a further quibble the soup made of it is called Palestine soup. The Forget-me-Not was originally the "Germander Speedwell," whose blossoms, falling of and flying away as soon as it is plucked, gave emblematic force to the name. It was known in the days of chivalry as the "flower of souvenance," and was embroidered into the collars of the knights, a fact still recalled by its German name, *Ehrenpreis*, Prize of Honour. About 200 years ago we find the name given to the Ground Pine, *Ajuga Chamæpitys*, whose nauseous taste once realised can never be forgotten. Finally it was seized upon by the river-side *Myosotis*, and forthwith sprung up a charming legend, created obviously to suit its latest identification—how that while two lovers loitered by a lake, the maiden saw and longed for the bright blue flowers, the knight plunged in to get them, but, unable to regain the shore, had yet agility enough to fling them into his lady's lap, and then, with a last devoted look and the words "forget me not," sank below the waves for ever.

Many names of plants contain the geography of their origin. The Canterbury Bell is obvious, so is the Guelder Rose. The Alexanders, a rare plant round Taunton, but growing in great quantities at Blue Anchor, comes from Alexandria; the Candytuft from Candia; the Elecampane, from Campania; the Medick from Media; the Caraway from Caria; the Walnut or Welsh Nut from the north of Italy, called *Wälsh* by the Germans. Peach is *Persicus*; Shalot, *Ascalonicus*; Spinach, *Hispanicus*; the Damson, rightly spelt as *Damascene*, tells its own tale, which is less clear in the case of the Dame's or Damascene Violet, a corruption extended and perpetuated, as often happens, by its Latin equivalent, *matronalis*.

All first attempts at classification, etymological or other, leave a large margin of miscellaneous items refusing to be ticketed or systematised; and there remain a few names falling under none of the categories which I have cited, yet too interesting to be omitted. Such is Apple, retaining its form in the Teutonic, Celtic, Slavonic, and Lettish languages, and springing apparently from the Sanskrit *ap*, water, which reappears inverted in the Latin *pa* of *Padus*, *po* of *Poto* and *Pomum*, meaning therefore the water fruit or juice fruit. Such again is Daffodil, the Daffadowndilly of Spenser and other poets. It is a combination of *sapharoun*, or Saffron Lily, with *asphodelus*, the old English Affodilly. With the taste for alliteration often shown in popular names the Sapharoun Lily blending with the Affodilly became by a mutual compromise Daffadowndilly, whence Daffodilly and Daffodil. Foxglove is the Fox's-glew, or tintinnabulum, a ring of bells hung on an arched support. Bedstraw was a plant much used for couches before mattresses were invented, and a species which when dry yields a pleasant scent is still called Lady's Bedstraw. Carnation is coronation, its flowers being used as crowns or chaplets, just as Campion is champion, gathered to crown the champions in a tournament. Cress is possibly from *cross*, its petals being cruciate; possibly from *crecere*, to grow, in token of its rapid increase. It was used in Chaucer's time, under the form of *kers*, to express any insignificant quantity.

"Of paramours ne raught he not a kers,"

from which comes, perhaps, the vulgar phrase, "I do not care a kers," though a yet ruder parallelism has since been manufactured to confuse its spelling and its etymology. Nettle is from *net*, to spin, indicating that its coarse fibres were used for thread in early times—an idea borne out by Hans Andersen's beautiful tale of the wild swans, in which you remember that the princess was permitted to redeem her brothers from their transformation by weaving them shirts of Nettles. Shamrock is from an Erse word signifying the little Trefoil. The story of its theological use by St. Patrick is of modern date, and it has been taken by various writers to represent the Watercress, the Wood Sorrel, the Dutch Clover, and the Black Medick. Irishmen are divided in the present day between the two last, which are sold on

* Lecture by Rev. W. Tuckwell before the Somersetshire Archaeological and Natural History Society.

St. Patrick's Day both in London and Dublin. The Snowdrop is so-called from its resemblance to the large eardrops worn by ladies in the sixteenth century, and represented often by painters of that period. The Tobacco was the Indian name for the pipe in which the weed was smoked, not of the weed itself; and Potato belonged at first to a tropical *Convolvulus*, and was transferred by mistake to the well-known esculent. The Gooseberry was the cross-berry, from its triple spine, which frequently takes the form of a cross. The Hollyhock is the cauliflour, hock being an old name for the Mallow, to whose order it belongs, and cauliflour, meaning Cabbage, either from its lofty Cabbage-like stalk, or, as in Cabbage Rose, with reference to its rich double bloom. The Laburnum closes its petals at nightfall like a tired labourer, and the Ozier is named from the oozy beds, which suit its growth.

I bring my list to an end, not because it is exhausted, but for fear my hearers should become so. I have picked only the most suggestive and curious of our many floral names, leaving an abundant gathering to many gleaners. One branch of the subject I have barely touched, the superstitious practices attaching to many of our wild plants, though not surviving in their names. I have left alone the interesting question of Bible plants, of the Hyssop, the Juniper, the Mustard-seed, the Lilies of the field, the burning bush, the Shittah, the Almaug, the Gopher, the curiously mis-translated cab of dove's dung, with the light thrown on their identity by the names given to them in the commentaries in our older translations. Nor can I do more than hint at the rich store of literary allusion to our wild flowers which abounds in all English poets, and the beautiful thoughts suggested to many of them by some particular plant. I should have liked to read you Chaucer's lines upon the Daisy, Herrick's on the *Daftodil*, Burns' on the Dog Rose, Shelley's on the Sensitive-plant, Southey's on the Holly, Wordsworth's on the lesser Celandine, Longfellow's on the Compass-plant. I should like to open volume after volume of Elizabethan and of later days—to enumerate and discuss the flowers with which Ben Jonson bids us "Strew, strew the smiling ground;" the "pretty pounce and chevisaunce," of Spenser; the "quaint enamelled eyes" that decked the laureate hearse of Lycidas; "the silver globes of Guelder Rose" which won the heart of Cowper; the "Hawthorn bush beneath the shade" of Goldsmith's lovers; the "slight Hairbell" which raised its head, uncrushed by the airy tread of Ellen Douglas. I should like to remind you of the lessons in natural theology which Paley drew from the "little spiral body" of the Dodder seed; of the star-shaped shadow of the Daisy which Archer Butler showed to Wordsworth, or how Linnæus, when he first saw the wild Broom in flower—

"Knelt before it on the sod,
For its beauty thanking God."

Above all I should love to turn with you the page of Shakespeare, to read of the grey dis-crowned head of Lear wreathed with "rask fumiters and furrow weeds;" of Perdita at the shearing feast, disparaging the streaked Gilliflowers as Nature's bastards; of poor distraught Ophelia distributing her Rosemary and Herb-of-grace; of Puck telling how Love-in-idleness was purpled with love's wound; of Titania gently entwining the "female Ivy and sweet Honeysuckle" round the sleek smooth ass's head of Bottom; of Helena and Ilermia, "a double Cherry seeming parted, two lovely berries moulded on one stem." For I should lay on you a spell mightier than I can forge myself—I should invoke allies before whom we all bow as the source of our intellectual happiness and growth; I should remind you how the most creative minds have drawn nutriment from these tenants of our hedgerows and hill-sides, and how the knowledge of their lore helps us in its turn to interpret the sweet thoughts and apt illustrations of the poets they inspired and delighted: how, if the aspirations of my Cambridge botanist were fulfilled—if the Daisy could become the *bellis*, the Strawberry the *fragaria*, the Honeysuckle the *caprifolium*, the Heather the *calluna*, the parting genius of romance and myth and association and folk-lore would be sent sighing from the domain of botany, and the richest and most attractive of the natural sciences would become the dullest and the most neutral.

In conclusion, let me disclaim all merit of originality in the ideas which have been put before you to-night. I have but attempted to bring together, with the

interest attaching to cumulative illustration, conjectures which have been started and discoveries which have been worked out by others. Scattered through the old-fashioned tomes of Cole, Lyte, Parkinson—through the pleasant pages of London, Pratt, Johns; above all in the most valuable work on popular botany which we owe to our Somersetshire naturalist, Dr. Prior, you will find all or nearly all that I have advanced. The flowers were plucked by other hands; mine has been only the *pia dextera* to sort and wreath them. *Nature*.

WHEAT, INDIAN CORN, AND POTATOS.

We take the following interesting remarks on these three main necessities of life from an able address on "Economy and Trade," delivered by Mr. James Caird, C.B., F.R.S., at the Social Science Congress at Aberdeen:—

WHEAT.

Wheat is the common food, which possesses all the elements necessary to sustain life and strength, the most generally palatable, and, notwithstanding the vast increase in its consumption, the cheapest article of food we possess. The hard-working poor are far more dependent on it and much larger individual consumers of it than the rich. If its price, like that of most other commodities, had risen with the increasing demand, our trade advantages over other countries would have been counterbalanced, and to a large extent lost. But the Wheat region has been designed, apparently, to be co-extensive with the progress of civilised man, and the more regular and extensive the demand upon it, the more ready and continuous becomes the supply, even without the stimulus of an excessive price. The average price of the quarter of Wheat for twenty years preceding Free Trade was 59s. 8d., and that of the last twenty years 51s. 4d., being a fall of 11 per cent. For the corresponding periods Barley shows a rise of 11 per cent., and Oats 9 per cent.; and yet, notwithstanding the fall of price, the supply of foreign Wheat has risen enormously, and continues to increase. Previous to 1860 the foreign imports of Wheat had not exceeded an annual average of 4,500,000 qr.; during the last five years they have reached an annual average of 12,400,000 qr. This is a fact of great importance when we consider the increasing population of the country, and the limited means we possess within it of increasing our supply of food. Not only do the consumers increase, but as their circumstances improve they individually use more food.

The common estimate of economists thirty years ago, that each person in the community consumed annually 8 bushels of Wheat, was a delusion. It was questioned by me in 1850, my estimates then showing that it could not much exceed 5 bushels. Mr. Lawes, to whose elaborate and judicious experiments the agriculturists of this country are so deeply indebted, carefully investigated this subject a few years ago, and showed conclusively that, at the time of which I spoke, my figures were the more correct. But he has also found that in a period of sixteen years before 1868 the average rate of consumption increased, each person having during the first eight years used 311 lb. of Wheat, and during the last eight 335 lb., or in the first period 5 bushels and a tenth annually, and in the last 5 bushels and three-tenths. In the first of these periods, 1852 to 1860, 232 lb. of this was home-grown Wheat, and 79 lb. foreign. These proportions have during the last five years undergone a great change and some increase. The home-grown Wheat annually consumed by each person is now 158 lb., and the foreign 183 lb. But three of these five years have yielded inferior crops, otherwise the supply of home and foreign would have been nearly equal. These figures show two very important results for the consideration of those who are concerned with the provision of the country. First, that the individual consumption of bread has increased; and, second, that we at present depend wholly on foreign countries for that increase, and for all further addition required by the annual increase of the population. For that addition an annual increase of Wheat equal to all the Wheat at present grown in Scotland would barely suffice.

The natural tendency of the gradually falling price of Wheat in this country since 1848, and the rise in that of Barley, Oats, and animal food, has been to diminish the breadth of our own Wheat. It is now

one-fifth less than it was twenty years ago. And the force of that tendency, in spite of the great increase of gold, shows the steadiness of its operation. There has been a yearly increase of consumers, with a larger individual power of consumption of bread, and at the same time an increase in the volume of gold—the representative of its value—and yet the price has declined.

But though we are already in so great a measure supplied with our bread by the foreigner, we run no greater risk of pressure than other countries on that account, probably less than most. For instead of being dependent on the sometimes fickle climate of our own land, we make all lands our tributaries, exchanging with them the manufactured produce of our mules and looms for the crude produce of their agriculture, on terms mutually advantageous. Either in the East or West there are every year abundant harvests, and we profit by them. Since 1873 the United States and Canada have given us half our supply of foreign Wheat. In 1872, with a bad harvest, their export fell one-half; but it made little difference to us, as the abundance of France and Russia filled up the vacuum at no greater cost. In 1871, France, which in 1866 had given us nearly one-third of all we required, could spare us nothing; but the plenty of Russia and the United States made good the difference.

During the last two years India has been sending us considerable quantities, which in the present year have mounted up to more than a tenth of our whole supply. The famine in Southern India may for a time interfere with this, but otherwise there is every reason to believe that the numerous cultivators of her fertile plains, having found a satisfactory market, even during a year of low prices here, will continue in still larger measure a trade so auspiciously begun. The foreign corn trade of this country involves the movement of 6,000,000 tons, worth more than £50,000,000 sterling, of immense value to all those countries which find ours the best and most constant market for their produce, but most enriching us into whose lap this wealth of natural abundance is poured. And even it from war some of the main sources of our supply should for a time be cut off, we have the means within our own boundaries of at once meeting such a contingency. We grow at present nearly 1,000,000 acres less Wheat than we did twenty years ago. We have only to revert to the acreage of 1856 to meet such a deficiency as would be caused by all Europe being shut against us. And, beyond that, we possess in our immense breadth of pasture land a never failing resource of stored-up agricultural power which could be at once applied to the production of corn, if from any circumstance that course became at the same time necessary and profitable.

INDIAN CORN.

Next to Wheat, in value and quantity, are our imports of Indian Corn, nearly three-fourths of which come from the United States and Canada. Last year there was a sudden increase upon all preceding imports of this substance from America, the supply jumping from 600,000 to more than 1,300,000 tons. Vast though this quantity appears, it is less than a twentieth part of the American crop. Previous to the Potato famine of 1846-7 Indian Corn may be said to have been quite unknown in this country. In 1847 500,000 tons of it were introduced into Ireland to feed the people, but it was not found palatable, and the imports quickly diminished, till in 1857 they barely exceeded 125,000 tons. It was not much more in 1867, but doubled in 1868-9, after the bad harvest in this country of 1867. It rose still further in 1875, after the bad harvest of that year; and in 1876, with another deficient harvest here, it doubled at once the highest previous importation. It is the cheapest article of food in the market, being at present little more than half the price of Wheat per pound, and its introduction in such large quantity greatly modifies the pressure which would otherwise be felt after deficient harvests in this country. It is next to Wheat in the extent of zone of production, and therefore capable of great increase should circumstances require it.

POTATOS.

The Potato crop is becoming more and more precarious. It is costly to grow, expensive in seed and manure, exhaustive of the land, and very liable to disease, and now possibly to the attacks of the Colorado beetle. The extent planted has declined nearly

one-fifth since 1871, while the imports of foreign Potatoes in the same time have risen from 43,000 to 300,000 tons. Germany is the great Potato growing country, whence we can always draw by a moderate increase of price whatever quantity we require. The annual crop in that country is twice as great, both in quantity and per head of population, as that of either France or the United Kingdom, but it is not exported till the price rises above the rate which it yields when made into spirits. In these, the three main necessities of life—Wheat, Indian Corn, and Potatoes—the field of growth and supply is so extensive that it has hitherto been found capable of meeting all the demands of a great increase of population without a permanent rise of price. It is very different with meat and other kinds of animal food, the increased consumption of which has led to a great rise of price.

BRITISH GARDENERS.

CHARLES ELWORTHY.

MR. C. ELWORTHY, whose portrait we publish to-day, was born at Bridgewater, Somerset, on April 29, in the year 1805. He commenced his career in the horticultural profession at the early age of twelve years, when he entered the gardens of — Sims, Esq., at Cannington, in the county of Somerset, and was placed under the tutelage of Mr. Rowe, the gardener. In this place he remained two years. At the age of fifteen he went to the gardens of R. Codrington, Esq., Bridgewater, under Mr. Eastlake, gardener. Mr. Codrington was the first gentleman who built a greenhouse and plant and Pine-stoves, also succession Pine and Melon pits, in that neighbourhood, heated in the old style—by flues, hot-water pipes having at that time not been thought of. He was very fond of his gardens and plants, of which he had a good assortment, of stove plants in particular, such as *Strelitzia reginae*, a rare plant in those days, which was well flowered; also *Renalmia nutans* [*Alpinia nutans*], which was flowered there, and at the time was said to be the first ever flowered in England. The gardens were at this time entirely under Mr. Elworthy's charge. Some Orchids, such as *Cymbidium aloifolium*, *Limodorum Tankervilleae* [*Bletia grandifolia*], and some few others, were grown, but Orchids were scarce in those days. Many other rare plants were cultivated, amongst them such as Cinnamon, Allspice, Ginger, Coffee. The plants were all well managed, as were also the Pines, which produced excellent fruit.

At the age of twenty Mr. Elworthy went into Mr. H. Lake's nurseries at Bridgewater for two years, to gain a knowledge of training and cutting wall fruit and other trees, and to be sent out to remodel old gardens, and lay out new ones. He was then recommended by his old master, Mr. Codrington, as gardener to Jeffrey Ellen, Esq., Recorder of Bridgewater, with whom he remained five years; after which he was recommended by Miss H. Trevelyan, eldest daughter of the late Archdeacon Trevelyan, and by Mr. Ellen, to the late Sir John Trevelyan, Bart., into whose service he entered at the end of March, 1832. At that time the greater part of the ground now occupied by the gardens at Nettlecombe was pasture land, but through the kind assistance rendered by the late Sir John, and the encouragement he has received from the present Baronet, Sir W. C. Trevelyan, the gardens have been brought to their present state, "which," he adds, "must be seen to be appreciated, as it would take up too much space in your valuable paper to enumerate the fine things that are growing here." Mr. Elworthy's name has long been associated with British Ferns, on which subject he remarks:—"It is well known, through Mr. T. Moore's *Nature-printed Ferns*, and Mr. E. J. Lowe's work on our *Native Ferns*, that I have added considerably to the many forms of British Ferns by the discovery of them in their natural state, and by raising new forms from spores."

Mr. Elworthy has been especially successful in raising new varieties of *Athyrium*, and of *Scopolendrium*, and very beautiful forms of both these genera bear his name.

TUBEROUS BEGONIAS.

NOW that these charming autumnal flowers, in consequence of their enormous increase as garden hybrids, are becoming better known and more extensively cultivated, with every prospect of attaining universal popularity, many of your readers will be glad of information (if experienced contributors will kindly give it) respecting the successful management of species which are still expected to be, one of these days, the parents of useful new varieties. Of *B. boliviensis* we already know all that we require to know; it is of original character, easy to grow and to multiply, and continues well worthy of being retained in our gardens, although it has given rise to offspring still more thrifty and showy than itself. But what are the merits of *B. octopetala*, and by what mode of treatment are they best called forth? Can any one speak well of its performances, either indoors or outdoors? Great things were said of it at its introduction, and while still sold at novelty prices; but it does not seem easily persuaded to bloom, and two years ago, at Ghent, they did not appear to expect much from it. Authentic news of the doings of *B. Froebelli* would also be welcome to many inquirers.

Amateur gardeners, especially those who reside at

a distance from any great horticultural centre, are now beginning to realise the truth of the lamented Van Houtte's appreciation, which, when first published, appeared to many to be an enthusiastic prediction rather than a sober judgment. "It is the *Begonia's* turn," he wrote, "to enter the arena! And here they come triumphant, all sails set, to demand a foremost place in our parterres! They do not indeed repudiate their chilly sisters, who display their charms only within a cage of glass; they readily yield to them the palm of foliage, so varied and so luxuriant; but they present themselves to astonish the world by their large flowers sparkling with every (?) hue, which, from the month of June to winter, by their constant, never-tiring succession, rival every other genus of exotic plants with which our gardens have hitherto been enriched.

"What does the gardener strive to do when he wishes honourable mention to be attached to his name? He tries to charm unceasingly the eyes of the master by the good taste of his decorations, and— which crowns the work—to give him the certainty when he returns to town, not only of leaving at his country seat a faithful guardian of his treasures, but an innovator who will assuredly present him next season with fresh ornaments, novel treasures, which will not cost him his eyes out of his head, and which

will give give a tenfold return for the money spent on them.

"If the master hesitates, if he refuses to risk more than a trifling outlay, at least let him allow his gardener the opportunity of proving how luxuriantly he might adorn his parterres by the acquisition of a few choice varieties of our tuberous *Begonias*; let him permit him at least to show the effect that would be produced by several dozens of mixed varieties, whose tubercles, taken up in autumn, can be stored away dry out of the reach of frost, like *Marvel* of Peru, *Guernsey Lilies*, *Erythrina*s, *Dablias*, and many others, which decorate the open ground all summer long, and take their rest in winter, sheltered from its severity in an outhouse or on a greenhouse shelf, for which there is no other use, unless the master obstinately persists in making his gardener a keeper of antique rubbish—of old *Geraniums*, for instance, which have served for the hundredth time, and which would be more advantageously employed in making leaf-mould for the growth of worthier successors."

Since then, the propagation of tuberous *Begonias* has gone on in geometrical progression. Beautiful, and temporarily expensive, novelties have been obtained, but old, good, and cheap varieties are still sufficiently plentiful for the amateur to see whether he

likes them, without their costing, as Van Houtte says, "his eyes out of his head." Seedling tuberous *Begonias*, hybridised or not, are now raised by thousands. The raisers naturally pick out the cream of the seedlings, give them names, and ticket them with respectable prices, selling the remaining commonly as hybrid *Begonias en mélange*, mixed varieties, at modest rates. Taking your chance of a small lot of these, a few really good ones will sometimes appear amongst them, because certain seedlings will not develop their full merits until after the raiser has decided against them as first-rate. He has not time to wait their convenience year after year. And here be it noted that the tubercles even of established favourites improve with age, blooming more freely, as well as making robust growth. But those who must have A 1 varieties only, do better to invest their money in a few undoubted excellencies than to run the risks of the lottery involved in hybrid mixtures, which nevertheless is interesting, and anything but ruinous.

In the *Gardeners' Chronicle* for September 8, p. 302, you mention, as brilliantly in flower at the cool end of the T range at Kew, *Emperor*, superior in habit to *Vesuvius*, and really one of the finest; *Kallista*, new, but with fewer branches (a great defect), though fine and distinct in colour; *Dr. Masters*, an earlier production, but still essential, no other having appeared with equal colour and length of flowers; *Orange Boven*, distinct and desirable; *Chelsoni*, profuse in bloom, and rendered most effective by its numerous branches; *Comet*, *Rosette*, *Vesuvius*, and *Prince of Wales*, all highly effective. *Starlight*, one of Colonel T. Clarke's hybrids, is valuable from its quantity of white flowers. But the success of these varieties under glass at Kew still leaves us in ignorance both of their price and of their fitness for bedding. I may, therefore, state that *Chelsoni* is excellent both for the border and the pot. The same of *weltoniensis* (obtained, if I mistake not, by Colonel Clarke), already recommended in these pages for conservatory decoration, and which does not seem to need absolute rest in winter. It has been sold by some French gardeners as *B. diversifolia*; but the true *B. diversifolia* (sp.?) is quite different, with lanky slender stems, especially indoors, and larger, less numerous pink flowers; outdoors, three or four tubercles can be planted to form a small group, supported by a stick to prevent breakage by winds. *Chambersii superba* may be highly recommended, both for foliage and flowers. *Pearcei superba* is a great improvement on the ordinary *Pearcei*; the yellow of the blooms is brighter and the velvety leaves have a striking effect, but the stature of the plant is too short to carry them out of the reach of splashing by rain, and therefore it is better retained under shelter in a pot. Some of these hybrid *Begonias* are apt to shed their male flowers, especially before they are opened. This bad habit may often be corrected by transferring the plant

from the pot to the open ground, which suggests that ample pot-room is favourable to indoor success. The record of B. Frœhelli flowering from seed sown this year, is interesting. The *Revue de l'Horticulture Belge* for February recommends that mode of propagating B. *semperflorens*, a good old sort, with vigorous shining foliage and abundant flowers, white in the shade and tinged with pink in sunshine. Plants so raised are said to be stronger and to flower earlier than roots which have rested during winter, and been made to sprout again in spring. E. S. D.

2-2½ inches long; ovary oblong-cylindrical, above 1 inch long; tube ½ inch long; segments ¾ inch long. Filaments twice as long as the segments, inserted below the top of the perianth-tube; anthers yellow, nearly 1 inch long. Style reaching to the top of the stamens.

A native of the provinces of Vera Cruz and Yucatan, and probably other parts of Mexico. A full account of the plant and its uses will be found in Dr. Engelmann's paper, as cited, and a recent description of it under the name of *ixtlioides*, with a coloured figure, taken from a specimen that flowered at Kew in

This last I know only from Dr. Engelmann's account of it, so I leave it where he has placed it as a probable variety of *rigida*. Doubtless using even the scale of species-limitation here adopted, and much more if we follow that of General Jacobi, it should stand as distinct. Of the species known in cultivation A. *excelsa* and A. *Houlettiana* should be compared with it. It was found in Yucatan by Dr. Perrine, and introduced by him into South Florida thirty or forty years ago, and is now naturalised plentifully at Key West and on the adjacent coast. Whether A.

FIG. 79.—AGAVE CORDEROYI.

THE GENUS AGAVE.

(Continued from p. 264.)

49. A. (*Euagave*) *Ixtli*, Karwinski in Salm-Dyck Hort. 1834, p. 304; Kunth, Enum., vol. v. p. 835; Jacobi, Monogr. p. 95. A. *Karwinskii*, Zuccarini, Kunth, Enum., vol. v., p. 837; Jacobi, Monogr., p. 33; A. *ixtlioides*, Hook. in Bot. Mag., t. 5893; A. *rigida*, Engelm. Notes, p. 28.—Shortly caulescent. Leaves 30-40 in a rosette, oblanceolate-spathulate, 1½-2 feet long, 2-3 inches broad at the middle, narrowed to 1½ inch above the dilated base, where it is 1 inch thick, rigid in texture, decidedly glaucous, but less so than in *lurida*, the centre ¼ inch thick, the pungent end-spine 1 inch long and decurrent a little down the margin, the rather distant chestnut-brown horny teeth ½ inch long. Scape 8-10 feet high, exclusive of the thyrsoid panicle, which is 3-4 feet long by half as broad, with the flowers in dense clusters; leaves of the scape distant, linear, adpressed; bracteoles minute, deltoid. Perianth greenish,

January, 1871, in the *Botanical Magazine*. It yields the Sisal Hemp of Yucatan, and runs into many varieties, of which the following are the principal:—

1. A. *rigida*, Miller; Jacobi, Monogr., p. 94; *fourcroya rigida*, Haworth; Kunth, Enum., vol. v., p. 843.—A small form, with entire glaucous leaves.
2. A. *elongata*, Jacobi, Monogr., p. 108; A. *fourcroyoides*, Jacobi, Monogr., p. 107; A. *ixtlioides*, Lemaire; Jacobi, Monogr., p. 237; A. *rigida* var. *longifolia*, Engelm., Notes, p. 28.—Leaves glaucous and toothed, as in the type, but running up to a length of 4-5 feet and a breadth of 3-4 inches.
3. Var. (?) *sisalana*, Engelm., Notes, p. 28.—Trunk short. Leaves pale green, not glaucous, 4-6 feet long, 4-6 inches broad, generally without teeth, but here and there bearing a few unequal, sometimes very stout and sharp teeth; terminal spine stout, often twisted, purplish black. Scape 20-25 feet high. Panicle 8 feet long by half as broad.

Ixtli be really specifically distinct from *lurida* in a broad sense I greatly doubt.

*** Leaves oblanceolate-spathulate, not glaucous when mature.

50. A. *excelsa*, Jacobi, Monogr., p. 238.—Shortly caulescent. Leaves about 30 in a rosette, oblanceolate, 1-1½ foot long, 21-24 lines above the middle, narrowed to 12-15 lines above the base, where it is ½ inch thick, rigid in texture, ¼ inch thick in the centre, green when fully mature, slightly glaucous when young, the pungent brow end-spine about ½ inch long; the side-spines distant, deltoid, brown-tipped, reaching ½ inch long, the face slightly channelled. Inflorescence unknown.

Of this I know but little. The above description is taken from a specimen in the Kew collection, received from Honduras. Its alliance is close with A. *rigida*. I have seen it in English collections under

the name of *A. Kellockii*, but it is totally different from the plant characterised under that name by Jacobi, which belongs to the *Subintegrifoliae*.

51. *A. Corderoyi*, Hort. Peacock (fig. 264).—Acaulescent. Leaves 40—50 in a dense rosette, rigidly erectopate, ensiform, $\frac{1}{2}$ foot long, 1 inch broad two-thirds of the way up, narrowed to $\frac{3}{4}$ inch above the base, bright green, the face rather channelled, the base $\frac{1}{2}$ inch, and the centre $\frac{1}{2}$ inch thick, the hard brown end-spine 1 inch long, the moderately close erecto-patent dark brown spines of the margin $\frac{1}{4}$ inch long. Inflorescence unknown.

This is a very distinct plant, which I cannot find described, and have seen only in the Peacock collection. Perhaps some of your readers can enlighten us as to its history. From all its neighbours it may be recognised at a glance by its very rigid narrow bright green leaves and by the shape of its prickles.

52. *A. Regaliana*, Jacobi, Monogr., p. 236.—Acaulescent. Leaves oblanceolate-spathulate, $\frac{1}{2}$ foot long, $2\frac{1}{2}$ inches broad above the middle, narrowed to $1\frac{1}{2}$ inch above the base, a light pruinose green, the face slightly concave, the end-spine dull brown, hard and pungent, the marginal teeth very minute, crowded, colourless. Inflorescence unknown.

This I have not seen in the English collections. It was described by General Jacobi in 1865 from a plant exhibited by Messrs. Glym, of Utrecht, at the Amsterdam Exhibition. Its alliance with *A. miradorensis* is obviously close, and I cannot, from the description, make out any distinctive character for *A. ananasoides*, De Jonghe and Jacobi, *Nachtfrage*, part i., p. 32. As before stated *A. Regaliana* is a name frequent in gardens for *A. horrida*. *G. Baker*.

(To be continued.)

ORCHIDS AT WHITCHURCH RECTORY.

AMONGST the many collections of Orchids that have of late years been formed in different parts of the country there are few equal to that which has been brought together at Whitchurch Rectory by the Rev. J. B. Norman, who is enthusiastic in the cultivation of these most fascinating plants. I had not seen them for about two years, and on going over early in June was really surprised at the extent of the collection, and still more at the number of scarce and beautiful varieties in flower, especially amongst the cool and medium temperature kinds. I found two houses almost exclusively filled with plants in bloom. The *Odontoglossum*-house is adjoining the dwelling-house, situated on the north side, and running parallel with it, and can be entered therefrom; and as the rest of the houses are connected with this the whole can be visited during all weathers without going out-of-doors, the convenience of which is at once apparent. This first house, in which were the principal lot of *Odontoglossum* and *Masdevallias* in flower, is 45 feet in length by about 12 in width. The back wall is covered with rockwork clothed with drooping Ferns and *Lycopodiums*, interspersed with Orchids in flower. On the front, as will be seen, is a stage about 3 feet wide. This is continued round the end and along the back, about half the length of the house. Here were most of the best *Odontoglossum*, but the greater portion consisted of *O. Alexandræ* and *O. Pescatorei*: of these there were over eighty strong drooping spikes, clothed with their lovely flowers, embracing every variety from almost pure white to the highly tinted and profusely spotted forms of these most beautiful yet variable of Orchids. Most of them were exceptionally fine kinds, selected from amongst hundreds which Mr. Norman has purchased as imported, and as they have flowered only the best and most distinct have been retained. The house is kept about 50° in winter, and correspondingly cool in summer. Many of the plants of *O. Alexandræ* had two spikes to one bulb. I noticed one with a couple bearing twenty-nine grand flowers. The *Masdevallias* were in themselves a sight worth seeing; they covered some 20 feet run of the stage, and comprise most of the kinds in cultivation. There was *M. Veitchii*, with nearly a hundred expanded flowers; *M. Lindemii*, with 120; *M. Harryana* in every shade of colour which this most sportive of plants assumes, from *M. sanguinea* to the bull's-blood variety and deep magenta shade of *M. purpurascens*; an extraordinary plant of *M. ignea*, with 200 expanded flowers; the rare *M. Benedicti*, bearing eighteen blooms. Others noticeable in this select group were *M. Trochilus*,

M. Peristeria, *M. elephanticeps*, &c. Interspersed over the house were a number of plants of *Epidendrum vitellinum majus* in bloom, the orange-scarlet of which associated with the *Odontoglossum* and *Masdevallias* produced a charming effect.

Adjoining this is the show-house, 45 feet by 13 feet, completely filled with Orchids in bloom (fig. 80) brought here from the different houses in which they are grown to prolong their flowering—to effect which the atmosphere is kept comparatively dry. The *Cattleyas* and *Lælias* were exceptionally well done; the large pseudobulbs, thick leathery leaves, and strong flower-spikes bespoke an abundance of healthy roots—a condition these plants are not always seen in. One plant of *Lælia purpurata* was bearing nine stout spikes, another had bulbs, independent of the leaves, 18 inches in length by 5 inches in circumference, the flowers proportionately large. There was a charming variety of *L. Brysiana* in flower. A magnificent specimen of *L. majalis* had on it fifteen of its exquisitely-colored blooms. *Cattleya Mendelii* was represented by many varieties, also *C. Warneri*, three plants of *C. Dowiana*, three of *C. gigas*, and the extremely rare and beautiful *C. Reineckiana*: the petals and sepals of this regal plant are of the purest white, the interior of the labellum rich magenta. *C. Mossiæ* was present in abundance in its numerous forms. There were in all over 300 flowers of *Lælias* and *Cattleyas*. One *Odontoglossum vexillarium* with seventeen flowers, and another with nineteen; *O. Roezlii*, with over forty blooms; *Oncidium crispum*, bearing eight spikes, some of which had crisy flowers each upon them; *O. Rogersii*, bearing its large golden-yellow flowers, $2\frac{1}{2}$ inches across; *O. divaricatum majus*, with five spikes, some of which were branched and 3 yards long; *O. Weltoni*, *O. fuscatum*, a fine form of *O. prismatocarpum*, *O. leucophilum*, *Odontoglossum citrosimum roseum*, *O. nævium majus*, *O. Reichenheimii*, with many long branching spikes; *O. cirrhosum*, *Cattleya Aclandias*, *C. Schilleriana*, *Dendrobium crystallinum*, with seven bulbs, 2 feet high, and full of bloom; *D. amœnum*, with its sweet violet-scented flowers. In this house likewise were numerous *Vandas*, *Aerides*, &c. Next is a house 60 feet long and 12 wide, divided by a partition in the middle. The first division contained large specimens of *Celogyne cristata* and other varieties, *Oncidium*, *Miltonias*, *Pleiones*, &c.; the second division is devoted principally to growing *Odontoglossum*, of which there are 2000 of *O. Alexandræ* alone, doing beautifully.

In the adjoining house, 30 feet by 13, the *Cattleyas* are grown collectively in excellent condition.

Next is the *Dendrobium*-house, completely filled with these plants in pots on the stages, and baskets suspended from the roof; noticeable amongst them was *D. Wardianum* and a fine example of *D. densiflorum*, just out of flower, that had borne fifty-four spikes, and most of the other kinds worth growing. *D. Ainsworthii* was nicely in flower. It is apparently a good grower and a free bloomer.

We now come to a house mainly devoted to East Indian species: *Vandas* and *Aerides*, as well as the other occupants, looked well, and promised to flower abundantly.

In the next house were some fifty plants of *Odontoglossum vexillarium*, many of them good examples, pushing up two or three spikes each; a number of *O. Roezlii*, eight plants of *Lælia anceps Dawsoni*, several specimens of the true old *Cattleya labiata*, select varieties of *Lælia elegans*, *Oncidium sarcodea*, with bulbs 10 inches long and very stout. Some of these had produced racemes of 150 flowers each.

In the adjoining house I noticed 250 plants of *Odontoglossum cirrhosum*, and some twenty-five *Oncidium macranthum*, *O. cucullatum*, *O. tigrinum*, with very large bulbs; *Pleione humilis*, equally well done; and *Cypripedium Schlimii*, growing vigorously. A part of the roof of this house is covered with *Maréchal Niel* Rose, that flowers freely every spring. The above-mentioned plants are grown under it, the temperature frequently falling down to 40° in the night during winter.

After passing through the houses and noticing the general health of the plants, I inquired where the hospital for the sick and diseased subjects was, as I have rarely seen such a quantity of plants with so few out of condition amongst them; but no such place exists here, which, with the excellent health and annually increasing strength of the plants individually, speaks sufficiently as to the treatment they receive being in accordance with their requirements. *Zed.*

Natural History.

LANDRAIL PERCHING IN A TREE.—My pointer flushed a landrail yesterday in a rough, grassy pasture adjoining a wood. Something then happened which surprised me. After taking a direct course edging the covert the bird reached the end of the field, and alighted in an Oak just within the wood. I have known a fox in a tree, but this was the first time, after many years' experience as a sportsman, that I have seen a landrail in such a position. It did not seem to suit him quite, and he sat, oscillating and uneasy, on the small branch upon which he had alighted till I drew within shot and bagged him. He was a fine bird, in capital condition. Is the landrail becoming arboreal, or was this particular specimen shy of entering the large wood which lay before him? *Subscriber, Sept. 18.*

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—Any hard-wooded greenhouse plants that remain out should at once be got into their winter quarters. Heaths ought to have the side lights of the house they occupy wide open during the day and night also, when the weather is calm and no signs of frost, with plenty of roof ventilation as well, as any approach to a close, warm atmosphere at once has a tendency to excite growth, which however little at the present season should be avoided. Tea Roses in pots have in most cases done well this summer since turned out, the more than usual humidity in the atmosphere having favoured growth, with less injury than ordinary from mildew or insects. Where the attention has been such as the plants require they are more than usually furnished with flower-buds. They should at once be got under cover, as exposure during frosty nights, or stagnation of the roots through excessive rainfall, will interfere with the flowers opening; ordinary greenhouse treatment will suffice to bring them into bloom, but nevertheless by the use of a little warmth the flowers will come finer, especially those of the more tender kinds. The unapproachable white-flowered *Niphetos* is generally seen in its best condition when subject to a little warmth; this with *Isabella Sprunt*, sulphur-yellow; *Duchess of Edinburgh*, bright crimson; *Souvenir d'un Ami*, salmon; *Catherine Mermet*, flesh colour; *Madame Villermoz*, white shaded with salmon; *Safrano*, apricot; *Souvenir d'Elise Vardon*, creamy white; *Jean Ducher*, lemon; *Madame de St. Joseph*, pinkish salmon; and the reddish crimson *Hybrid Perpetual*, *Général Jacqueminot*, are a dozen that may be relied on to give satisfaction for winter flowering. If there is any trace of insects or mildew upon them they should be thoroughly cleansed before taking indoors; give a good syringing with Gishurst at 3 oz. to 1 gallon by way of making sure, as if the eggs of aphides or spider exist they soon come to life when taken inside, and are much more difficult to deal with after the plants have commenced making growth, which is naturally a deal softer and more tender than that which has been produced in the open air.

SOFT-WOODED GREENHOUSE PLANTS.—Bulbs: Nothing tends to weaken bulbous plants of any description more than keeping them out of the soil after they evince signs of wanting to commence growth—*Hyacinths* are especially liable to suffer in this way. These bulbs this year are in a much less satisfactory condition than usual, owing to the genial weather that existed whilst their growth was being made, but, as in most cases of a similar character, some kinds have suffered more than others, and whatever partiality may be entertained for any particular kind or kinds, the roots of which are in an indifferent state, it will be well to substitute for them others that are stronger; and withal, so far as possible to make up for their weaker condition, it will be advisable to get them potted before they evince, by the pushing of their roots, a disposition to grow. The old practice of giving these and other deep-rooting bulbs large, deep pots was, no doubt, through an impression that by the greater extension thus allowed to the roots in their natural downward course corresponding advantage would be gained by the production of stronger flowers, yet such is by no means the case, and I have never found that the flowers were in the slightest degree either stronger or better for the

use of these ugly deep pots, or by employing large ones at all. If other essentials to their well-being are present, as satisfactory results may be obtained from bulbs grown in 6-inch pots as in those that are much larger, which, so far as both room and appearance goes, is an advantage. The same holds good with Narcissus, Tulips, and Crocuses, only that the latter, when their wants are well attended to after blooming until the leaves naturally die down, flower well in subsequent years turned out in the borders, and when very small pots are used the roots are apt to suffer from want of water; when the blooming is over, consequently, a little more pot-room proportionately may be given to these. I should advise all, even for the latest blooming, to be at once potted and placed under conditions most favourable to a free and full development of root-fibre previous to bringing them into bloom, without which, especially in the case of such as are forced, it is useless even from the strongest bulbs to expect good flowers. A bed of coal ashes with a few inches under the pots so as to exclude worms, and the material filled in and covering them to a depth of 4 or 5 inches, will suit them. A cold frame with the lights altogether off unless in excessively wet weather, or without the frame, merely using a few shutters to protect them should excessive rainfall ensue, will answer for them. It is seldom that bulbs receive too much moisture in this way, yet I have known the root-fibres injured during a very wet autumn, as these, like all other plants when in pots, cannot bear moisture in the soil to an extent that does little or no injury when planted out. Pelargoniums in pits and frames where they receive insufficient light should at once be got into a house and stood where they will get a full complement. The early shoo-out plants placed for a time in pots of a less size will shortly be in a condition for moving into those they are to bloom in, and in the case of young plants will have made sufficient growth to require the shoots stopping. This should be done before they have advanced too far, especially where it is desirable to furnish them with an increased number of branches. Chrysanthemums this season, even where very little stopping has been resorted to, are unusually late in setting their flowers, and where late stopping is practised to the injurious extent that it is sometimes carried out, the plants will not flower at all satisfactorily. Directly the bloom-buds are large enough they should be fully thinned out, and some provision ought to be made for giving them shelter under temporary lights fixed overhead, or with a canvas covering that can be drawn over them when there is likelihood of frost; as if in their present backward condition they are for some time yet taken in, even to the most airy light houses, they will be almost certain to become a prey to mildew; the foliage in many cases is very soft, and if the parasite makes its appearance, they should at once be destroyed with sulphur. *T. Baines.*

FRUIT HOUSES.

THE CHERRY HOUSE.—The sashes which were taken off this structure, as indicated some time ago, need not be replaced for another month, except the demand for space for sheltering plants from the effects of frost be actually required. If this be the case, and the house is brought into requisition for this purpose, select such subjects for inmates as only require merely casual protection, so that the trees may still have the benefit arising from a full and free course of ventilation being continued. By this time the foliage on the trees will have become almost fully matured, and, therefore, the use of the syringe over it may be discontinued. Proceed in pruning the trees as soon as the leaves are off. This matter will not involve much time if the stopping as indicated throughout the growing period had due attention. As the red-spider is sometimes troublesome on these trees it will be prudent to employ every means at this season to extirpate such an enemy. If the mussel-scale, to attacks of which Cherry trees are very susceptible, be present on the trees, dress them over with a mixture consisting of sulphur with a little slacked lime to afford consistency, and enough glue to make it stick firmly, to which should be added a little strong tobacco-water or Gishurst Compound. If the trees in pots have not already had attention in the way of repotting, dis-rooting, and surface-dressing, these matters should be seen to as soon as the chief part of the leaves are off the trees, using for a compost for potting pure fresh loam with a little grit added, and rich material for top-dressing. If these trees have a covering of straw or long manure placed around the pots to protect them from the action of severe frost they may still be left outside and fully exposed. *G. T. Miles, Wycombe Abbey.*

VINES.—Muscats and other late-keeping Grapes which have reached perfection in colour and finish will now require a gradual reduction of temperature to insure their keeping fresh and plump. A mean

night temperature of 56°, with a rise of 10° by day, will suffice. Keep the atmosphere dry. Remove all surplus growths and laterals, and ventilate freely in dry weather. Protect ripe Muscats from the direct action of the sun by laying sheets of tissue-paper over them, and examine occasionally for decaying berries. Mid-season houses from which the fruit has been cut, also Vines that have not hitherto carried fruit, should now be divested of laterals up to the pruning bud. Carefully preserve the old leaves. Apply fire-heat in the daytime if necessary, and keep the house cool at night. When top-dressing, lifting, and relaying of roots or additions to existing borders are contemplated advantage should be taken of the present fine weather for the completion of the work. Use good turfy loam, bones, and burnt or charred garden refuse thoroughly mixed, and mulch with about 4 inches of fresh horse-dung. Let the borders have the full benefit of October rains, and protect with dry fern or shutters towards the end of the month. If not already done, Vines intended for starting in November should now be pruned, in order that the wounds may heal before the house is started. No rule can be laid down for pruning, but for early work it is always safe practice to cut back to a firm plump bud. Let the Vines be well cleaned and dressed with a composition of soft soap, sulphur, and tobacco-water in proportions of 1 lb. of the former to half-a-pound of soap and 1 pint of strong tobacco-water. If mealy-bug has to be contended with, add a tablespoonful of turpentine. Reduce to the consistency of thick paint, and apply with a painter's brush. Thoroughly cleanse the glass and woodwork, whitewash the walls, and replace old mulching and surfacings with the compost above recommended. If the addition of fresh varieties is contemplated, the bottle system of grafting, efficient and simple, may be adopted as soon as the wood is ripe. Judging from the form in which Golden Queen has been shown this season we may conclude that growers have not yet succeeded in doing it justice. Venn's Seedling has again set, swelled, and coloured well with me, the skin being thicker and the footstalks shorter and stouter than those of Muscat Hamburg. It will in all probability prove a much better keeper than Grape than that fine, but capricious variety. Black Alicante is becoming a general favourite, as it sets, swells, and colours well under the most adverse treatment; but in quality it is inferior to Kempsey Alicante or Black Morocco. Madresfield Court, now acknowledged to be one of the best early and mid-season Grapes, is worthy of a place in every house except the latest. *W. Coleman.*

CUCUMBERS.—The glorious autumnal weather we are now enjoying is all that can be desired for winter Cucumbers, as it admits of a free circulation of air with a minimum of fire-heat. The earliest hatch of plants, intended to give a supply of fruit up to Christmas, are now swelling off clean healthy fruit, much superior to that obtained from old plants in pits and frames; and as the latter will now be required for bedding plants, salading, &c., they may be cleared without delay. Where bottom-heat is obtained from hotwater-pipes and fermenting materials combined, the latter should be thoroughly worked, to get rid of noxious steam before it is taken into the pit. In placing the pots let them stand on sads of turf fairly over the bottom-heat pipes, and place the fermenting material firmly round them. For winter work the ball of the young plant should be kept up nearly level with the rim of the fruiting-pots, and the compost used may be somewhat lighter than that recommended for summer. After planting, the pit should be kept close and moist for a few days, when more air may be given, and treatment the reverse of coddling will be followed by the most satisfactory results. Maintain a minimum temperature of 68°, and dispense with fire-heat as much as possible by closing about 1 P.M. As days decrease in length and brightness overhead, syringing must be less frequent; but a genial growing temperature may be maintained by damping the paths, walls, and surface of the bed. If the stock is short, young plants may still be raised from seeds or cuttings for coming into bearing after the end of January. Keep them near the glass in a light pit, where they will make short-jointed sturdy growth, one of the most important points in the successful management of winter Cucumbers. Take advantage of this fine dry weather for getting under cover a good supply of turf and old lime rubble for winter use. *W. Coleman.*

KITCHEN GARDEN.

The Cauliflowers sown last month will now require attention, as they will be large enough to prick out, and they should not be left standing too thick in the seed-beds, as the great object is to obtain a short stocky growth, which will enable them to withstand better the vicissitudes of winter. For very early work the strongest plants should be selected, and potted in small pots, which should be plunged in a bed of leaves, under glass, and kept well ventilated. After they have made a start another batch should be

pricked out in a frame, on a gentle bottom-heat of leaves and dung, keeping close for a day or two, and then removing the lights entirely every fine day, but drawing them on at night and in wet weather, taking care to ventilate freely both night and day for some time; the remainder may be left in the seed-beds until they are large enough to prick-out at the foot of south wall. As we may soon expect frosts, Tomatos should be frequently gone over and the ripe ones cut off; and if not required for use at once they will keep for some time, if stored on shelves in vineries, or other glass erections, with little or no artificial heat; and as soon as frost is certain, it is a good practice to cut the whole crop of any size, and store them away on shelves, secure from frost, to ripen. No time should now be lost in finishing off the whole of the plantations of Lettuces, intended to stand through the winter, of which the old black-seeded Bath Brown Cos is one of the earliest and best for the purpose. Hicks' Hardy Green and Stanstead Winter Cabbage are also good sorts. The latter is also good for planting in frames, so that they can be protected through the winter; these will be found very useful for salads in early spring. This important crop is now so much in request all the year that no chance should be lost for want of a little seed; and a bed sown now in a warm sheltered corner will often fill up a gap in the spring after inclement winters. Finish off, likewise, the planting of the varieties of Batavian Endive; these are much hardier than the Moss Curled, and more to be depended upon for winter use. Take every opportunity of very dry weather to continue the tying-up of Lettuces and Endive for present use, and also be looking forward to the tying of the crop intended for storing away in pits for winter use. Continue the sowing of red and white Turnip Radishes on a warm border in light soil; and also at the same time sow a two-light frame on a warm border without heat, which, with one sown later on upon a gentle hot-bed, will keep up a good succession for some time. The early-sown Carrots will now be fit to take up for storing, the later sown may remain in the ground for some time yet, in fact until they begin to show signs of maturity by the leaves turning yellow; the last sown will of course be left in the ground all the winter, but, as they are liable to be eaten by grubs, it is a good plan to move the surface 2 or 3 inches, and stir in some soot and lime amongst them. Salsify and Scorzonera will now have attained maturity, and should be lifted and stored away in sand in a cool and dry place, secure from frost. Where Bracken is very plentiful one of the very best of houses for the storing of these and all other roots, such as Carrots, Red Beet and Potatoes, may be made by marking out the required space and building all round it walls of Brake 6 feet thick and 7 or 8 feet high, to allow for sinking; a number of poles should be laid across the opening, and on them some brush-wood, like what is used for Peas, and then the Brake piled on in the form of a ridge and thatched; during the process of building every effort should be made to compress the Fern as closely as possible, and, when the erection has stood for a week or so to settle, cut a doorway through with a sharp hay knife; this may have temporary double doors, and in severe frost the space between filled with Brakes or straw. Dig a trench all the way round to carry off the water from the roof, and you have a cheap erection, than which nothing could be better adapted for the required purpose, being unaffected by the extremes of cold or heat, and having an equable temperature so much to be desired in both fruit and root house. I may mention that it is by some practical men preferred to build the stack solid, like a haystack, and then cut out the interior after it has been well settled down. The present has been a very favourable season for the germination and development of weeds, and every effort should be exerted at once to exterminate them, either with the hoe in dry weather, or, what is still better, turning them under with a steel fork, amongst crops of all sorts, wherever possible, which will give all the benefits of surface stirring, combined with that neat appearance so desirable in this department. *John Cox, Redleaf.*

GENTIANA ACAULIS.—This fine old plant was formerly much used in "old-fashioned" flower gardens. It was generally planted as an edging for beds of hardy perennials, and when grown in a suitable soil and situation was, during April and May, a beautiful object, from the brilliant azure of its flowers. I have grown it for some years in tufts on the front margins of beds and borders of hardy flowers. It is one of those plants that likes a pure air and a good loamy soil, moderately moist. It is easily increased by parting the roots; but, in order to flower it finely, it must not be too often parted or transplanted. The tufts produce an abundance of flowers after they have been two or three years undisturbed. With an annual top-dressing of decayed leaf-soil or manure they will continue to flower for some years undisturbed. It is a plant that merits a place in every garden. *M. Saul, in "Florist and Pomologist."*

THE
Gardeners' Chronicle.

SATURDAY, SEPTEMBER 29, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	Oct. 1	Sale of Dutch Bulbs at Stevens' Rooms. Royal Horticultural Society: Meeting of Fruit and Floral Committees, at 11 A.M.;
TUESDAY,	Oct. 2	General Meeting, at 3 P.M. International Potato Exhibition at the Royal Aquarium, Westminster (three days).
WEDNESDAY,	Oct. 3	Sale of Dutch Bulbs at Stevens' Rooms. Sale of English-grown Lilies at Stevens' Rooms.
THURSDAY,	Oct. 4	
SATURDAY,	Oct. 6	Sale of Dutch Bulbs at Stevens' Rooms.

THE SEASON FOR PLANTING being close upon us, we shall be doing good service by calling the attention of those of our readers who may be about to plant or transplant to this fact, which the lingering life of the fleeting flowers is apt to make us forget, till a sharp autumnal frost comes upon us as a reminder that summer is departing, and winter rapidly approaching. Even when the fact does appear to be realised we are prone to play with the few remaining weeks, in which much of this work can be done to the greatest advantage, as if time would wait our leisure or convenience.

When work of this kind has to be performed there are always certain preliminary considerations to be thought out, and sundry arrangements to be planned, and this thinking and planning is in the case of inexperienced persons apt to be deferred till the time for active work has come, and then some of the best part of the season is lost in discussions and consultations, which would have been better cleared out of the way at an earlier period. It is to this that we would particularly call attention at the present moment, in order that the plans and changes to be adopted may at once be settled, and the fine weather of October be taken advantage of to prosecute the work.

Where trees and shrubs for ornamental purposes have to be planted, there can be no question that the earlier weeks of autumn offer the best time for carrying out the work, taking a general and common-sense view of the matter. There may be, and of course are, hardy free-growing subjects that may be planted at any time during the winter if the weather is open and favourable; and there are many cases in which, from unavoidable circumstances—especially where builders stop the way—the best part of the autumn cannot be taken due advantage of. Setting these aside, however, there is much planting delayed for weeks after this date, which would be better done at once; and in such cases we advise that all preliminary considerations should be decided on, the area to be occupied marked out and prepared, and the occupants selected, so that they may be bought in as soon as possible, and put into their places without any delay when they are procured.

Then, again, with fruit trees, the sooner in the autumn they occupy the positions they are intended to fill the better both for roots and tops. But especially does this rule apply to any established or partially established trees which may need the corrective of a slight check to the roots, such as autumn lifting and replanting supplies. The past summer has in many districts at least been favourable to wood development, and the light crop of fruit, which in too many cases is the sum of the year's results, will have been rather favourable than otherwise to this kind of development. Moreover, young trees which are about to be introduced from the nurseries cannot be had too soon in the autumn. There is then a better selection to be made, as they can be had on the principle of "first come first served;" and the trees have also a better opportunity of taking hold of the new ground, and laying the founda-

tion of a more healthy and vigorous growth when the time for growth comes next spring.

The great advantage that may be looked for from early planting may no doubt be mainly traced to the warmth which has been stored up in the soil during the summer months, in consequence of which the roots begin active life at once, instead of lying dormant or dying, as they too often do when put into damp chilly soil in winter. Besides, the tops are not now drained by parching winds and a piercing atmosphere as they are when planting is done in spring. All plants like bottom-heat if it be not carried to excess; and the summer's sun just brings about that condition of the soil as to warmth which is congenial to the trees—both useful and ornamental—that thrive in our climate, the tenderer ones no doubt deriving the most decided advantage from it.

There is something too in the immunity from damage by frost, which autumn lifting, and consequently autumn planting, brings in its train. As evidence of this, we need only mention the fact that lifted and transplanted Roses often escape uninjured, while those which remain unmoved are either severely punished or destroyed.

Our object is not now, however, so much to point out what to plant as to impress upon our readers the desirableness of at once settling their plans and completing their arrangements for the planting season, so as not to waste precious time in these preliminary matters during the next few weeks, in which rather the spade should be kept actively employed. The same considerations apply to the planting of hardy flowers. The sooner any that have to be moved are put into their permanent places the better.

— A CORRESPONDENT has been good enough to direct our attention to our statement at p. 369, that the "leaves and flowers of Casimiroa are like those of the Orange." We ought to have mentioned that we were referring to botanical kinship, not to superficial appearances. In truth the leaves of Casimiroa are compound and studded with transparent oil-cysts, as in the Orange. Superficially, there is not much resemblance to the leaves of the Orange.

— The THIRD INTERNATIONAL POTATO EXHIBITION will be held at the Royal Aquarium, Westminster, on Wednesday, Thursday, and Friday next. We are informed that a very extensive display may be expected, for, notwithstanding the prevalence of disease, many of the careful cultivators of Potatoes have lifted heavy crops. We are requested by the committee to beg the trading firms who take an interest in the show to abstain from overloading it with gigantic trade announcements, for it is not desirable that advertisements should be more conspicuous than Potatoes.

— Are the old SINGLE WHITE AND SINGLE LILAC AURICULAS in cultivation, or are they quite lost to gardens? We are led to ask this question because enquiries are being made for them, but they are not forthcoming. The double white variety which was announced in Continental catalogues two or three years ago has not yet been seen, in England at least, and applications for it have met with no response. The taste for these fine old border flowers is being surely revived, hence the enquiries that are being made. There are in English gardens some capital single yellow Auriculas that make excellent border flowers, and some of the Rev. F. D. HORNER's eccentric yellow seedlings are well deserving cultivation as border flowers.

— A good deal of attention has of late been given to the MEDICINAL EFFECTS OF COCA (Erythroxylon Coca), and MATÉ OR PARAGUAY TEA (Ilex paraguayensis) has also received some consideration. The introduction of this as a beverage has, it appears, been recommended recently in Brazil, under the name of "Sterva Maté," a name which we do not remember having seen before. It is said that the cultivation and preparation is largely carried on in Brazil, and it is extensively imported from the province of Parana to the neighbouring countries of

Uruguay, Paraguay, and the Argentine Confederation. It is referred to as a matter of regret that this beverage has not become an article of commerce for the European markets, seeing that those who have used it bear testimony to its being an excellent substitute for either tea or coffee. "In its nature" it is said "more fortifying and alimentary, and far more wholesome, it can be bought at a price so moderate that it would easily be within the means of the poorest inhabitants of Ireland or Scotland, and there can be no doubt that if it were once known it would be extensively used in place of the far more expensive and constantly adulterated beverages of tea and coffee." We are further told in the notice of the substance from whence we quote the above, that a small sum of money has been appropriated by the Minister of Agriculture in Brazil, for the purpose of making this useful plant more known in Europe.

— A NEW ILLUMINATING OIL is promised to the world by a M. GUILLEMARE, who has brought to the notice of the French Academy of Sciences his discovery of the presence of three kinds of oil in the resin of *Pinus Pinaster*. These oils are said to be very rich in illuminating power, burning with a bright steady flame, and giving a brilliant light. So confident is M. GUILLEMARE of its power and brilliancy that he has proposed it for use in lighthouses and similar places where a powerful, steady light is required. No fear is entertained regarding the supply, as this Pine is very largely cultivated in many parts of Continental Europe, and in the extensive sandy and marshy plains along the Bay of Biscay, and reaching inland between the Garonne and Adour, it is especially abundant, being planted for the twofold purpose of affording shelter to the country and protecting it from the loose, driving sand. The resinous products of the trees are diligently collected by the people, and form their principal staple of industry, and it is from the resin so collected that M. GUILLEMARE proposes to prepare this new oil.

— A correspondent of a contemporary, in reporting a local show, mentioned that certain ONIONS were of good form, each bulb measuring fully 16½ inches in diameter. A humble cottager to whom this statement was read, remarked, suggestively, "Them wur *Innis!*" with a stare of admiration that might well be excused, considering that each one is thus made to measure 4 feet 1½ inch in circumference.

— From the Colonists we learn, on the authority of the *Indian Tea Gazette* of Calcutta, some facts concerning TEA CULTIVATION IN THE EAST. China-Assam Tea, it seems, is a new feature in the trade, and quite an unlooked-for competitor for Indian Tea planters. It shows that the Chinaman does not intend to leave the field of Tea cultivation to India without a fight for existence. Japan Tea has made as rapid and as wonderful progress as Indian Tea during the past ten years. The annual production has already increased from nothing to 25,000,000 lb. in a few years, with every prospect of increasing even more rapidly than Indian Tea. The cultivation of Tea is progressing most rapidly in all parts of the East, tea-gardens having been established in Ceylon, Madras, Barmah, Singapore, and Java, in all of which it is proved that the climate is well adapted for this branch of culture. At the Cape and in Natal Tea plantations have also been established, while in South America there is a talk of growing it on a large scale. Coffee-leaf Tea, we are told, is likewise a feature in the trade, which may develop into a troublesome opponent of Indian Tea, experiments having been made in Ceylon with not unsatisfactory results.

— Messrs. LITTLE & BALLANTYNE, Carlisle, had the honour of supplying a plant of their new WELLINGTONIA GIGANTEA PENDULA NOVA, to be planted on the occasion of H.R.H. Princess LOUISE's visit to Isel Hall, Cockermouth, the residence of the Hon. P. S. WYNDHAM, M.P.

— Many of the finest AUTUMN-FLOWERING HERBACEOUS PLANTS may now be noted at KEW. *Linaria dalmatica* has long produced a profusion of bright yellow flowers, which it will continue to do for some time. *Galatella dracunculoides* may evidently be selected as the best of its genus. *G. cana* and others are also in flower. *Helianthus argyralis* will this year be very floriferous, though it cannot be more

handsome than at present, every stem being clothed from near the ground to apex with graceful recurving leaves. Some of the best Asters are in bloom, though others equally fine have yet to expand. Those of the present are *A. sericeus*, *A. cricoides*, *A. patulus*, *A. laevis*, *A. turbinellus*, *A. spectabilis*, *A. Shortii*, *A. Amellus*, and its variety *bessarabicus*. *Anemone japonica* is in great beauty, so also is *Pyrethrum uliginosum*, one of the finest of tall herbaceous plants of this season.

— A specimen of HARRISON'S NEW MUSK recently seen at the nurseries of Messrs. JOHN

run of Orchidaceous species, they are being fast elevated, as the florist would say—degraded, as the botanist might say—to the rank of florists' flowers. However startling this assumption may at first sight appear to many, it can nevertheless be supported by irrefragable evidence. Take any popular species, and what do we find? Why, this, that the variety that will best stand the severe scrutiny of a florist's eye is by far the most valuable. The same law that enacts that form, substance, colour, and general symmetry shall take precedence over the general ruck of florists' flowers, holds good among all popular Orchids. Any one can find this out by going to market to purchase the rari-

any down the line of species in any catalogue, and some sorts will bring as many pounds at a sale, if they be known to be super-excellent, as others will bring shillings. And so it is with *Cattleyas*, with *Vandas*, with *Aerides*, with *Saccolabiums*, and with every popular Orchid. It may be form, or substance, or colour, or exquisite symmetry, or all combined, but the individual that possesses all these in greatest degree will be run upon by the *savans* in the matter of flower-value. I have, therefore, he adds, "to congratulate the "general assembly" of florists for the good work they have done, are doing, and doubtless will continue to do, in bringing together the above

FIG. 80.—MR. NORMAN'S SHOW-HOUSE FOR ORCHIDS (SEE P. 398.)

PERKINS & SONS, Northampton, was remarkable for its size and the rich head of flower it carried. The plant was some 2 feet in height, by as many through. It was of symmetrical form, and remarkably well bloomed. It promises to make such an effective exhibition plant, and to be so far in advance of the old Musk as a specimen, that window gardeners should take it in hand, and cottagers be encouraged to cultivate for show. It is already becoming a useful market plant.

— Mr. ANDERSON has recently in the *Florist* started the somewhat novel idea that ORCHIDS ARE FLORISTS' FLOWERS. Notwithstanding, he says, the grotesqueness of form and feature of the general

ties, not the rarities of species only, but the rarities among varieties of species. The fact is, so innumerable are the importations of recent years, and so very numerous the varieties of species, that two-thirds of the poor varieties—poor from a florist's point of view—are all but unsaleable; at least, if people buy them, it is only to get rid of them as soon as possible after they have proved themselves. When he began cultivating Orchids, he was most anxious to secure anything in the way of a species, no matter what. Now-a-days collectors find it to be both their interest and satisfaction in every way to secure first-rate varieties, many times at whatever cost. Take *Odontoglossums*, for instance, no matter whether it be *Alexandra*, *Pescatorei*, *triumphans*, *grande*, *citrosimum*, *cirrhosum*, or

racess of plants, from the commonest border flower to the most aristocratic Orchid, so as to subject them all to severe eye-criticism. It is only in this way that the best can be taken and placed, and the worst left and uncertificated. There is doubtless much truth in this view of the question, notwithstanding the sneers with which "florists' flowers" are sometimes visited.

— The ZONAL PELARGONIUM VESUVIUS seems to be of a remarkably sportive character, more so than most sorts, besides being, as it no doubt is, one of the very best of the scarlets for bedding purposes. From it sported *Wonderful*, a semi-double of the same colour, and having both the good properties of dwarf growth and abundant blossoming of its parent,

with the doubleness of the flowers superadded. Then came *New Life*, Mr. CANNELL'S, white striped scarlet, which is very constant to its markings, and when well established is really a striking flower. Now we hear of a salmon-lake sport, from the same stock—*Vesuvius*—in every way identical with it except in colour.

—Mr. CANNELL tells us that he has just obtained a further advance towards a *YELLOW PELARGONIUM* in the form of two brilliant flame-scarlet varieties, both of which are marked with distinct rays of yellow. Jealousy, which has hitherto been the most Auburn of our pale orange-scarlets, is said to have a dull and ineffective appearance by the side of these novelties.

—Like its prototype the common Elder, the *GOLDEN ELDER* proves to be a good plant for town gardens. During the summer season its leaves present a gay array of deep golden tints, which are exceedingly effective when judiciously placed for contrast with dark-leaved subjects. Just at this season, perhaps, the colouring may be somewhat suggestive of the early fall of the leaf, but the bright and brilliant tints of its summer clothing amply compensate for this minor drawback. It has been during the present season one of the gayest of the shrubs planted in the gardens on the new embankment at Cheyne Walk, Chelsea.

Florists' Flowers.

BEDDING AND BOUQUET DAHLIAS.—While tender plants are taking on a sombre and washed-out appearance, owing to the cold and rain, some late summer flowers are wonderfully bright and effective, especially the bedding and pompon Dahlias and the Marigolds. The Dahlias are particularly effective; the plants are not only laden with blossoms, but they shine out brightly against the leaden skies as if defying the advancing shades to do their worst. At the Royal Nursery, Slough, Mr. Turner has planted out lines of bedding and bouquet Dahlias as edgings next the walks to plantations of show Dahlias, &c., and when seen in this way one comes to realise something of their great value for decorative purposes.

I was astonished with the large number of blossoms produced by some of the bouquet Dahlias. There is first a remarkably fine branching habit, and from this come hundreds of flowering shoots laden with flowers. Mr. Turner said he has been cutting heavily from some of the plants, but the act of cutting the flowers only served to bring out the wonderful freedom of bloom in a remarkable degree. The bedding Dahlias have also been so much improved that they, too, are very floriferous and continuously so.

We have long looked to the Hollyhock to supply an appropriate background to the broad borders which front lines of shrubbery in many large gardens; but the terrible disease, which has been very destructive in many places, notwithstanding the summer has been cool and moist, has worked such havoc that gardeners are using the Dahlia in preference for this purpose. A few of the free-flowering taller growing Dahlias might be used as a background, and between and in front of these the bedding and bouquet Dahlias would come in admirably; they might also be dotted about in the borders as single specimens, and also be used to fill up the centre of large beds.

Of the bedding Dahlias proper, the most effective were *Crimson Gem*, rich crimson, with an excellent upright growth; *Drap d'Or*, pure yellow, very good indeed; *Faust*, shaded dark maroon, very effective; *Flora Macdonald*, primrose-yellow, very pretty; *Hilda*, blush rose, a very pleasing variety; *Leah*, a good show flower, and an excellent bedding kind; it has a capital erect habit, and shows off its fine yellow flowers to the best advantage; *Mont Blanc*, pure white, one of the very best of this colour; *Prince Frederick William*, crimson, very free and effective; *The Pet*, a capital fancy variety, very dark maroon, with a distinct white tip; *Yellow Pet*, pure yellow, very fine, and of a dwarf compact habit; the *Old Zelinda*, crimson-purple, upright, and very free; and *Rising Sun*, intense scarlet, dwarf and free. The foregoing twelve varieties represent the very best bedding forms in cultivation.

Of the bouquet Dahlias, all of which have small, compact, and very interesting flowers, the following can be highly recommended:—*Amelie Barberre*, flesh,

tipped with rose, very pretty indeed; *Baby Waite*, pale lilac, very free; *Bird of Paradise*, deep scarlet, very good; *Burning Coal*, yellow, with scarlet tip, very bright and effective; *Butterfly*, orange, heavily tipped with claret, very pretty; *Coronet*, blush white, tinted lilac, very good; *Dove*, white, tipped with delicate rosy lilac, a charming variety; *Dr. Schwebes*, rich scarlet, very good; *German Favourite*, crimson-lake, very pretty indeed; *John Sandy*, orange, shaded yellow, remarkably good; *Little Arthur*, orange-scarlet; *Little Beauty*, crimson-red, occasionally tipped white, very pretty; *Louis Rodani*, deep shaded lilac, exceedingly pleasing; *Mdlle. Valentine Faconet*, white and red striped, really a fancy bouquet Dahlia, charming and effective; *North Light*, bright scarlet, very good; *Prince of Lilliputians*, maroon, fine and free; *Startler*, a pretty light flower; *Triumph*, bright scarlet, very free, and one of the best of this colour; *Vesta*, an excellent white; and *White Aster*, with curious quilled florets, very pretty, free and good. *R. D.*

Apiary.

PRESENT WORK.—We would strongly advise all our friends to make a complete survey of all their stocks during this month. It may appear superfluous to examine all the stands carefully, but we have found a few minutes spent upon this labour each autumn amply repaid. In many apiaries which have been in existences say ten or fifteen years, the supports underneath the hives have gradually, though unobserved, been decaying; especially is this the case just above the ground line, but most bee-keepers never seem to think it needful to look over the stands. How easily when partially decayed the wintry winds blow them over, thus occasioning sad loss; most frequently the entire stock is lost, or rendered useless. Thus our advice, if followed, will in this respect not be regretted.

Most people, when making alterations in the garden, often change the situation of the apiary. If this be done, and the old stand be an old-fashioned bee-bench, holding several hives, let this be discarded at once and for ever, and instead thereof let every stock be placed on a separate stand. This may cause a little more expense in the change, but it will be repaid in the working of the apiary, for it will certainly prevent all loss from robbing, and probably the loss of queens, this meaning also loss or destruction of the entire colony.

No time should be lost in transferring condemned stocks to stronger hives; it is well to take all the second swarms, and mix the driven bees the same evening with stocks which have a sufficient supply of food to last over the coming winter. Our French bee-keepers call this "marrying hives." It is not a new-fangled system, as we have been frequently told by old cottage bee-keepers; it has been adopted in this country for at least a century, though we are willing to confess it never seems to have become well known, and evidently it has been only partially successful. We have made most of our best paying stocks from condemned stocks alone; these were placed about the month of August into empty skeps, and liberally fed. They quickly make the best of a bad job, for we find bees never sit down to repine when things seem bad with them—they rapidly set to work to repair all their losses, building new comb; it is then filled with syrup and sealed over for winter consumption, just the same as honeycomb. These stocks also come forth the following spring, healthy and vigorous; as a rule, much stronger than the old colonies. *R.*

ENMITY OF QUEEN BEES.—The rivalry of the queens is considered the primary cause of bees swarming, yet "W. K." announced at p. 204 that he found "five reigning queens at once in the same colony," and invites information on the subject. Need I say it is a common thing to find several young queens in a colony after the exit of the first swarm, but shortly one only is supreme. However, for the sake of those unacquainted with the *rationale* of swarming, I cannot do better than give an extract from the Rev. Dr. Dunbar's reply to a letter of mine in the *Gardeners' Magazine* on the calling of the queen bee, and add some observations on the subject. He said, "When the first laid of these eggs is hatched, and the larvæ or worm then produced is about to be transformed into a nymph, and before

the royal cell so inhabited is finally closed—a period occupying about eight days—the old queen leaves the hive with the first swarm. Those left behind are then without a head, and it is not till the fifth, sixth, or seventh day, according to circumstances, that the senior of the young queens leaves her cell; instantly on her emerging she flies to the cradles of the remaining royal brood and eagerly attempts to tear open the cells, and destroy their inmates. But the working bees interpose most effectually, guarding the cells with the most determined firmness, and repulsing the violence of the queen without any ceremony; for I have seen on such occasions half a dozen bees hanging close on her skirts, one hauling each leg or wing, and forcing her away from the spot; at every repulse the discomfited queen stands sulky hard by, moving her wings across her back without extending them, and utters the well known 'peep, peep,' sounds expressive of her anger and irritation at her deadly attempt being frustrated; after a minute or two have elapsed she repeats her wrath in the same cry. And this scene of violence continues almost without intermission for three days, sometimes longer, when the queen, irritated at last beyond endurance, traverses the hive in a state of great agitation, communicates that excitement to the workers, and finally leaves the hive with a great mass of the population. This forms the second swarm. The same process goes on with the next in seniority of the royal brood, provided the population be abundant, but at shorter intervals of time, corresponding with the interval between the laying of the royal eggs." I observe, however, that such is not always the case. Often after swarms come from weak hives it depends more on the time when the queens are bred, or the state of the weather; but such puny swarms not only weaken the colonies, but are worthless, except they are united to other stocks. In fact, the propensity of bees to increase their kind by swarming accords with their instinct to be the same as when adapted to the warmth of their original climate. *J. Wighton.*

Notices of Books.

Lehrbuch der Gartenkunst, oder Lehre von der Anlage Ausschmückung und künstlerischen Unterhaltung der Gärten und freien Anlagen. Von H. Jäger. (Text Book of Garden Art, or Theory of the Laying-out, Embellishment, and Artistic Maintenance of Gardens and Public Pleasure Grounds.) 8vo, pp. 687. Berlin and Leipzig: Voigt, 1877.

When a man spends thirty years in the preparation of a work, and his whole occupation during that period is of a nature to enable him to improve and refine his earliest ideas and thoughts, it is not unreasonable to expect that he has produced something worthy of the serious attention of those to whom it is addressed, because there is no surer way of gaining knowledge than by attempting to teach others. This is practically, as the author informs us, the history of the present book, and, as he very modestly puts it, the character of it has not suffered therefrom. Mr. Jäger is, however, not before the public as an author for the first time, having long been favourably known to the students of German garden literature; and most of his previous writings are upon different branches of the same subject. Moreover, his reputation as a landscape gardener does not rest upon what he has written, but rather upon what he has carried into practice. It is clear that in a short notice like this it is impossible to attempt a critical examination of the entire work, and, therefore, it will be limited to allusions to certain parts. Before entering upon this a passage from the author's introduction will give an idea of the way in which he has treated the subject:—

"Respecting the contents of this book," he says, "I have few observations to make. In the first and larger part the foundation of the entire theory is fully laid down, so that in the succeeding practical parts theoretical discussions and reasons are avoided; references to the proper sections being all that is required. Consequently special weight must be attached to this part; for he who would pass it over will remain an empiricist, and, in fact, has no need of my book. There is also the critical history of garden art (second division of the first part), which contains much instructive matter deserving of notice, to which I direct the particular attention of

the reader. Whoever is ignorant of the phases an art has passed through in its development will never thoroughly comprehend it; but whoever has mastered the theoretical and historical portions may confidently go his own way, as every artist must; for, with the exception of the universal principles and laws of the beautiful, there are no fixed rules to be followed in works of art. Talent must reveal itself in its own way, and in the art of gardening, which is bound up with so many obstacles and conditions in the way of utility, means, situation, the true artist will design an original plan for every new work. In our art copies are objectionable, and, indeed, usually impossible."

Even after this statement one is scarcely prepared for the total absence of plans and illustrations. Such is the case, however, and it is doubtful whether the author has exercised a wise discretion in this matter. The text is admirably arranged for ready reference, being in three parts, each part subdivided into sections and paragraphs with special headings, which are all enumerated in the excellent paged table of contents. The first part or division is devoted to the definition, historical retrospect, and present state of garden art. Discussing what garden art is, it is briefly defined as the art to mould any piece of ground or buildings destined for pleasure, according to the laws of beauty, and embellish it with plants, and so maintain it. But this is regarded as very inadequate, and the author proceeds to a more detailed conception, preceded by some observations on what in gardening is not art. Garden art, as treated in this book, "can be no other than a plastic art," and landscape gardening is regarded as one of the fine arts. But the general term "landscape gardening," was rejected as a title of the book because there are many other artistically designed gardens which cannot be called landscape gardens. Nevertheless, Mr. Jäger would employ the title "landscape gardener" in preference to any other, because the labours of those who practise the profession are chiefly connected with essentially landscape gardening. This paragraph is followed by others on the relations of the art to other arts, the definition of a garden from an artistic standpoint, and auxiliary aids to garden art. Then comes the historical portion, which is very fairly written, and commendably free from bias and prejudice. Blame and praise are meted out with impartiality, and it is not difficult to perceive that the writer possesses a most refined and artistic taste, which he earnestly endeavours to inculcate or awaken in others. The history of the gardens of the pre-Roman era, of the Romans, of the Middle Ages, of the Renaissance, of the Baroque period, of the period of the French style, is briefly sketched, winding up with the modifications the latter underwent in different countries. The Dutch get the credit of having banished the last trace of Nature from gardens previous to the fall of the regular style of gardening and the origin of the landscape or natural style. The blemishes of Le Nôtre's creations, as well as their redeeming points, are pretty fully discussed. Speaking of the French style, he says:—"One general consequence of this was the building of pleasure castles and villas in the plains. The taste for natural beauty was lost to most people. The castles on the heights, where there were glorious views, were deserted in favour of the plains, where there was space for canals, ponds, and large gardens. Frequently they built in the midst of a pine forest, so that they might be more completely shut in."

Naturally the part relating to the origin and development of real landscape gardening would interest an English reader, and we shall be pardoned for dwelling a little more fully on this, especially as a large share of honour is due to our countrymen on this score. Indeed, the name of "English style" is very generally used for it on the Continent. Our author fully recognises the praiseworthy position taken by the English people in initiating this reform, and we are obliged to agree with him in what he says (p. 83) respecting the more recent gardens at home. It runs thus:—"We have already enlarged upon the state of the gardens of Great Britain. So high a degree of excellence admits of few changes, and is not favourable to the development of talent. Where nearly everything is perfect, genius slumbers. England can, therefore, with the exception of Sir Joseph Paxton, the creator of the new Chatsworth and the architect of the Crystal Palace, produce no great name, although there were, and are still, many distinguished garden artists." Everybody will admit the justice of these remarks, and if the writer has erred, it is certainly on the side of leniency.

A concise sketch is given of the development of the art in England, with mention of the principal actors, from Lord Bacon to Pope, Kent, Brown, and Chambers, &c. The English style has taken a firm root in Germany, and one of the most gigantic undertakings in the way of landscape gardening of recent times was commenced by Prince Pückler, at Muskau, in 1816. He spent some years in England, and made himself thoroughly acquainted with all of the most celebrated examples of landscape gardening; and after his return home he devoted nearly the whole of his life to beautifying his estates. Unfortunately his enthusiasm carried him too far, and in 1845 he was obliged to sell the now celebrated estate at Muskau in Lausitz. Some few years later he retired to his seat at Branitz, where he also made extensive alterations in the formation of lakes and hills. One ridge is 60 feet and another 70 feet high, but taken as a whole the park at Branitz exhibits many defects.

The comparatively recently laid out gardens of Paris are critically examined, and their merits and faults, according to the author's views, enumerated. The defects noted are—mighty changes of the ground where there was no necessity for them, executed for the purpose of producing something novel, but unsuited to the character of the place; grand ideas often run into insignificant details, because large areas have been handled as small gardens; attempts at exceptional conditions in Nature which are difficult or impossible to carry out; disregard of true (so-called picturesque) natural beauties, negligence of details in the plantations, misconception of the real beauties of flowering and foliage plants, &c. But although this appears rather a lengthy list of defects, much more is said in praise of the work recently executed by the French. On the other hand there is a great deal of truth in the remark that indiscriminate and servile imitations of these grand undertakings have resulted in many miserable failures. Jäger specially deprecates what Barrillet-Descamps has executed in "England, the home of good taste in landscape gardening," and also in the Prater at Vienna. A paragraph on deviations in the style of gardens rendered necessary by climatal conditions and the mode of living of the inhabitants is, though brief, full of sound advice to the inexperienced gardener. It insists on fundamental rules being observed under all circumstances, and at the same time points out certain inevitable modifications in different temperate regions. Thus in most parts of the Continent it is impossible to have large expanses of green turf as in England or Scotland, and, on the other hand, there is a greater need of shade. The section headed "Considerations on the general attributes of a garden, and fundamental rules of their application," is divided into twelve paragraphs, entitled—1, size and its influence (apparent size); 2, situation (geographical and local); 3, unity, harmony, variety, novelty, contrast, relation, or comparison; 4, animation; 5, form and colour; 6, light and shade; 7, perspective or appearance; 8, reality, suitability, utility; 9, utilisation of the material at hand and the surroundings; 10, boundaries; 11, character and tenor; 12, the beautiful and picturesque. Under the section on the school and sphere of operations of the gardener as artist, practical designing and modelling is strongly recommended for winter evening work, and directions given how it may be profitably carried out. Travel, of course, is considered indispensable to complete the education. The second division is devoted to the consideration of the employment and form of the constructive materials of a garden, and it contains numerous passages that we should like to reproduce. Not but what most of it has been said and written and repeated over and over again, but from what we see every day offensive to good taste, these things cannot be too often brought forward in a journal devoted to the instruction of gardeners. There is one thing to be said, however: gardeners are by no means answerable for all the monstrosities and anomalies existing in the gardens under their care. To parody a celebrated character, some people have got lots of money and no taste. What Mr. Jäger has to say under the head of "fountains and waterfalls" might be studied with advantage by the authorities who have made the "finest site in Europe" ridiculous with their puny squirts. Fountains in public places should always be grand and monumental, says Jäger, and in all cases where they are introduced they should be in harmony, in size, character, &c., with their surroundings. Everybody will accept this maxim. But we do not agree with him respecting the introduc-

tion of mythological figures and water animals with water spouting or trickling from their mouths; and we would prefer the former to the latter, and these very sparingly used. Imitations of real animals vomiting water are not pretty to look at.

The second part, of about 200 pages, is on the carrying out and maintenance of gardens; and the third part, gardens and embellishments for particular purposes—as large public gardens, parks in cities, public squares and promenades, cemeteries, fruit parks, zoological and botanical gardens, school gardens, churchyards, hotel gardens, railway station gardens, &c. Already the limits of an ordinary notice have been exceeded, and yet there are many features of this book deserving of mention. The idea of an orchard planted for effect, or, as the author terms it, with some qualifications, a fruit park, though not new, has nowhere been fully carried out. Doubtless, with all the material at our disposal, an orchard might be made very attractive as well as useful. Chestnuts, Walnuts, Fig, Mulberry, and other trees associated with the commoner orchard trees, and Grape Vine, Berberry, &c., would afford as great a variety as could be wished. But, as our author says, such a park is neither an orchard nor a park, and is unsatisfactory, and only to be indulged in under exceptional conditions. *W. B. Hemslay.*

The Villa Garden.

CREEPERS AND OTHER PLANTS ON WALLS OF HOUSES.—How rarely these are planted with anything like judgment. On a wall of spare dimensions against which some good, useful, but rather slow-growing creeper should be placed, such as the Escallonia, Pyracantha, Cistus, &c., or some that might be pruned back pretty hard at the end of the summer, such as Clematis, Rose, &c., one sees *Wistaria sinensis*, the common Virginian Creeper, *Lonicera brachyopoda*, and other fast-growing subjects that require a world of attention to keep them snug and orderly in appearance. The *Wistaria* and Virginian Creeper are rare things for covering high and wide walls; but they are altogether too rampant and wild to be of service where only a small space of wall has to be hidden. Besides they are often put into shallow soils, in which they simply exist, and are never else than shabby.

It often happens that an entirely new house is taken, but with the garden altogether bare. A neighbouring jobbing gardener is called in to advise, and his intelligence rarely gets beyond *Wistaria*, *Honeysuckle*, *Virginia Creeper*, and *Gloire de Dijon Rose*. He plants these anywhere and everywhere, they are his stock plants, suitable for all positions, soils, and sizes of walls; and if they are not constantly kept nailed securely, they are blown to pieces by the wind. Only a few days ago we saw a house-front covered with a Virginian Creeper of many years' standing that had made a dense growth, but a violent gust of wind took it, and tore several yards of it from the wall, disfiguring the plant and leaving ugly gaps in the leafy garniture of the walls. The plant was so torn by the violence of the wind that no nailing up would make good the breaches, and it was found best to pull it down altogether. The common Virginian Creeper should not be planted against ordinary sized dwellings. True, it is an old favourite, and it is one of the most rapid agents in converting bare brick walls into masses of verdure, but it is unsuitable for our purpose for the reasons above set forth. And how much better it is to plant *Ampelopsis Veitchii*, or *A. Roylii*, if there is any real difference between them. Here we get an elegant dark and somewhat cut foliage, which clings to the wall by the aid of very powerful vegetable fangs or suckers put forth by the branches as they find their way about the walls. It is certainly not so luxuriant in growth as the common American species, but when established it soon covers a good space of wall, and gains in strength as its energies are multiplied. We saw this on the north side of a country residence a few days ago, and being well established in suitable soil it was making headway, and gradually covering the whole side of the house. Of other good things to go on a restricted space of wall we may mention *Berberidopsis corallina*, a member of the *Berberis* family—a climbing shrub with pretty crimson flowers, but rather tender; and, as it requires some protection during winter, should be on a sunny south wall.

Berberis Darwinii is a vigorous grower, bearing an abundance of dark apricot-coloured blossoms, but it can be cut back as desired, and but little nailing is required. The bright coloured flowers are succeeded by an abundance of plum-coloured berries, and the evergreen foliage is quite elegant in appearance. *Berberis dulcis*, with its very pretty nodding yellow flowers, may be used in the same way. The Clematises are so well known that little description is necessary, but for flowering in early spring *C. Standishii* and *Miss Bateman* should be planted, and for summer blooming *Jackmanni*, *rubella*, *Madame Grangé*, and *lauginosa nivea*.

On one Villa residence in a good suburban road near London, lined on either side with a good class of residences, one house has growing on its north-east corner a good plant of *Ceanothus deatatus*, and, though many of the houses are covered more or less with flowering plants, the one with the *Ceanothus* tops the whole of them in real effectiveness when the plant is in full bloom. At all times it has a pleasant evergreen foliage, but when the branches are radiant with the pretty lilac flowers the sight is one of special attractiveness. *C. rigidus* is perhaps one of the best for the purpose, and *C. Gloire de Versailles* is a remarkably fine subject; there is a charm of novelty about them, and it is a little monotonous to observe a row of Villa residences having nearly the self-same climbing plants placed against the walls. The common Gum *Cistus* makes a capital plant to go against the walls of a house; it is of slow growth and always evergreen, and the large white flowers with the handsome purple blotches in the centre are very handsome indeed; true, they do not last long, but they are freely produced. The common Gum *Cistus* does well in a cold and exposed spot, and is not over fastidious in the matter of soil. We saw the other day a piece of low wall against which was a good plant of the common Gum *Cistus*, and a well established plant of *Fuchsia Riccartoni*; and at one end a plant of *Clematis Jackmanni*, and at the other one of *C. rubella*. The wall not being more than 5 feet in height, the Clematises are cut down close to the ground every year, and when they commence to grow in spring the leading shoots are pinched back about twice. A great profusion of bloom results. There are spaces between the plants which are filled up during summer with plants of yellow and scarlet *Tropeolum Lobbianum*, and there is thus obtained a succession of flowers during a good portion of the summer. This combination may serve to suggest others. There are also other things besides those named suitable for planting against walls.

And it too often happens that these subjects are imperfectly planted, and they fail in consequence. Instead of remembering that these plants have to perform a service extending over several years, and providing the necessary sustenance in the way of good soil, a hole is dug out and the plants placed in the soil without much regard to its fitness. This is a great mistake. Then the plants often get almost dried up for want of water in hot weather. It is often forgotten that plants against walls require more water than those planted in the open ground, and when it is not forthcoming the plants take on a wo'ul appearance. The great danger is want of moisture at the roots during the time the plants are establishing themselves. When they become thoroughly set in the soil, and the roots have found their way beyond the bounds of the hole in which they were placed, their safety from harm through drought is more certainly assured.

CURRENT AND SULTANA CULTURE AT PATRAS AND SMYRNA.

The following notes on the culture and history of Currants and Sultanas were collected during a recent tour in the Levant. I am indebted for most of the statistical facts to Mr. Wood, Her Majesty's Consul at Patras, and to my friend, Mr. R. Barker, of Smyrna. Respecting the origin of these two forms of seedless Grapes, or the existence of sub-varieties, I could obtain little information. The Patras Currant was, however, grown as far back as the reign of Queen Elizabeth, when Sir Walter Raleigh is said to have had a sort of monopoly of its importation to this country. Neither the Patras Currant nor the Sultana Raisin appear to be intrinsically very distinct from numberless other varieties of small Grapes; their special seedless character, which is correlative with the diminished size of the berry, may have originally been

due to local circumstances of soil and climate, producing partially abortive blossoms and the absence of seed. The pollen of the Patras Currant is, however, fertile. I am informed by Mr. Barron, that in experiments at Chiswick made in crossing Black Hamburgs with the pollen of the Patras Currant and other seedless Grapes, hybrids were readily produced, partaking to some extent of the seedless and other characters of the male parent, but crosses could not be obtained in the other direction. The seedless character is by no means stable, as the Currant vine of Patras (*Σραφίδα* of the modern Greeks) frequently produces here and there a seed-bearing berry or small Grape in the bunches of seedless Currants; indeed, in some localities, the tendency to reversion to the Grape is very marked, and I am informed that an attempt to introduce the culture of Currants into the neighbourhood of Leghorn failed from the tendency of the plant in three or four years to produce a seed-bearing Grape.

The geographical range of the successful culture of the Currant vine is very limited. Patras is its metropolis, and of the 86,500 tons exported from Greece in 1876, 71,000 tons were the produce of the Morea, including a few grown in the neighbourhood of Mesolonghi on the north side of the Gulf of Patras, and the balance of 15,500 tons was exported from the Southern Ionian Isles, including Zante and Cephalonia, a few being also grown in Santa Maura; whilst Corfu, which is within sight, produces none at all, though the Grape is successfully cultivated there for wine.

Again, the quality and value of the Currants grown along the north coast of the Morea varies to some extent. Those produced in the district including Patras, Vostizza, and Corinth, command the highest price, and the quality falls off south-west from Patras towards Kalamata. The general production of Currants is increasing, the exports of 1876 having been greater than in any previous year. The crop was, however, exceptionally fine, as well as that of almost all other agricultural produce in Greece.

The produce of the several Currant-producing districts fluctuates; the export from the Ionian Islands is said to be declining, Olive culture gradually replacing that of the Currant vine, but the decrease is more than made up by the enlarged production in the Morea. The falling off in Zante is supposed to be partly due to increased cost of culture incidental to the Vine disease, but this would also apply to the Morea, where the crop is increasing; and the diminished exports from the Ionian Islands may perhaps be due to the excessive export dues, as the *ad valorem* duty of 19½ per cent. formerly in force under the British protectorate is still kept up, whilst on the mainland the fiscal imposition amounts to but 16s. a ton as "dimes" or Government tithe plus an export duty of 1s. 6d. a ton. The cultivation of the Olive and Currant vine in the same district also clash, as the labour demands of the two crops occur simultaneously, and any slight local advantage to the one over the other would tend to a gradual replacement.

The produce, gradually increasing on an average of years, fluctuates much with the season; in 1853—one of the years of the most severe attack of the oidium—the exports fell off to 2700 tons, the reduced supply coming mainly from Corinth. Since 1853 the oidium has been gradually mastered, and the production has progressively increased to over 86,000 tons per annum.

The Currant-producing district consists of a narrow belt of country bordering the coast, the vineyards for the most part are within 100 or 150 feet of the sea level, and the general limit of cultivation is lower than that of the Grape, rarely exceeding 400 feet in altitude.

CULTURE.

In travelling through the Vine districts of Europe the great variety in the methods of culture and training cannot but arrest the notice of the tourist, and many of the variations must be more a matter of habit or fashion than necessitated by local circumstances. The cultivation of the Patras Currant-vine includes several specialities that I have not observed elsewhere, and presents in the best cared-for vineyards unusual finish and detail.

Propagation is effected by long cuttings buried nearly a yard where the soil is sufficiently deep, or in shallow soil they are laid in horizontally for about 2 feet and then turned up. The cuttings are supposed to root at every joint, and the depth to which they are inserted is for the purpose of reaching the moist

subsoil in times of drought. Propagation is also carried on by grafting on other varieties of the vine.

The vines are planted in rows about 6 feet apart, a single shoot being trained vertically to a temporary stake about 3 feet high; this ultimately forms the permanent stock, and in a few years becomes sufficiently strong to be self-supporting. From its summit the young wood, consisting of six or seven shoots radiates, and each of these is headed in between December and February to four or five eyes, so that the stock has about thirty fruit-bearing points, producing collectively from fifty to ninety bunches.

The new growth radiates umbrella-fashion from the summit of the stock to the ground, and the only training required by this method of culture is the insertion of an occasional prop or support under the heavier fruit-bearing shoots.

Young plants commence to fruit about the third or fourth year, and produce a full crop about the seventh year. The ultimate cost of this system of training after the permanent stocks have become self-supporting must be much less than that of the staking of the annual shoots of the Vine from a low stool pursued in most of the French vineyards. In the best cultivated Currant vineyards at Patras extreme neatness of detail and high culture prevail. After the ripening of the year's wood in the late autumn or early winter the roots of the vine are partially bared, the soil being heaped up between the rows, and after a thorough dressing with goat's manure it is levelled down early in April. One of the special points in the culture pursued at Patras is the "ringing" or incision of the bark, which is done once a year by a small sickle-like knife specially made for the purpose. The process of dividing the bark was introduced in the year 1851, and is said to much increase the weight of the fruit, theoretically from the downward flow of sap being arrested and thrown into the berries. In the culture of Smyrna Sultanas this process was unpractised up to the time of my visit, but will, I believe, be tried as an experiment.

I was surprised at the gross growth of the Currant vine produced by the liberal culture pursued at Patras. The long shoots are nipped back at the end of June, and the redundant foliage reduced by the removal of part of the leaves two or three times during the period of growth.

The harvest commences about July 25, followed by successive gatherings extending over three or four weeks, the fruit on the secondary shoots maturing somewhat later than the main crop. The drying occupies from ten to twelve days, and the berries commence separating from the bunches in six or seven days. The former process was to spread them out on a bare plot of ground, specially smoothed and flattened for the purpose. But a cleaner method is now taking its place, and in some of the vineyards the drying is effected in wooden trays 6 feet long by 3 feet wide, sufficiently deep for a single layer of bunches. Much economy of labour is thus effected in the handling. The fruit is kept clean and free from grit and stones, and in the event of wet weather during the harvest the trays of fruit can be readily gathered up in piles over which light wooden roofs are placed. The stalks are cleaned from the fruit by winnowing.

PRODUCE AND VALUE.

The weight of the crop varies considerably. In some vineyards it only reaches from 300 lb. to 400 lb. per *stroma*, equivalent to from 900 lb. to 1200 lb. per acre, in others it reaches to from 900 lb. to 1400 lb. per *stroma*, equivalent to from 32 cwt. to 37 cwt. per acre, of dried fruit. In 1876 12 acres in the neighbourhood of Patras produced 15 tons of Currants, or about 25 cwt. per acre, worth at Patras about £20 per ton.

The value also varies considerably both with the quality and the season, ranging from 15s. or 17s. 6d. to 25s. per cwt. free on board at Patras. In the years 1851, 1852, and 1853, when the crop was almost wholly destroyed by the oidium, the dried fruit realised as much as from 60s. to 70s. per cwt.

The value of the year's crop generally bears a large proportion to the actual cost of culture, and as in our Hop gardens, the result is speculative. As an example, from a holding of 12 acres at Patras in 1876, the crop of 15 tons realised about £300, on which the expenses of culture and harvesting were but £85; but this was an exceptionally good year, and against the balance of £215 gross profit, interest on capital and a share of the preliminary expenses of establishing the vineyard and the loss on the first four

or five unproductive years would have to be deducted. The wages of both men and women during the harvest range from 1s. 10d. to 2s. 2d. a day, and at other times the women receive about 8d. a day.

DISEASES OF THE CURRANT VINE.

The oidium, which scourged the vineyards of Madeira and parts of Europe five-and-twenty years ago, fell with extreme severity on the Curraot vines of Patras and the Ionian Islands. It reduced the crops in the years 1851, 1852, and 1853 to less than a tithe of the original produce, the results in 1851 and 1853 being exceptionally disastrous. In 1853 the exports diminished to 2700 tons, most of which came from Corinth, and the total crop was absolutely destroyed with the exception of the fruit on a few of the lowest branches which happened to come in contact with the ground. The process of sulphuring has gradually stamped out the disease, and the exports since 1853 have gone on progressively increasing up to the present time, last year's exports of 86,500 tons never having been previously exceeded. The process of sulphuring is systematically conducted. The first application is made on the young shoots, sulphur is again applied to the young fruit, and for a third time before ripening when the fruit is nearly full grown.

The vines also suffer from the occasional attack of a small caterpillar, and in the Island of Zante especially they are liable to injury by a small beetle known under the local name of "seathari" which attacks the buds. They reach the vine from the ground, and their approach is arrested by tying a bunch of hay round the stem.

"SULTANAS" OR "SMYRNAS."

The small yellow aromatic Grape, called Zekirizidico by the Turks, appears to have been known in the neighbourhood of Smyrna between 200 and 300 years. Apart from the fact of its being seedless it possesses no marked character to distinguish it from several other varieties of small yellow Grapes, and I could not ascertain that any sub-varieties of it are known.

The general character of the cultivation is similar to that of the Greek Curraot, though the Smyrna vineyards are scarcely so neat in detail as the Currant vineyards of Patras. The Vines are planted in rows 6 or 7 feet apart at intervals of 3 or 4 feet, but the stocks are lower than those of the Patras Currant, and instead of being trained to a single leader they form an irregular branching stump from 1 foot to 2½ feet in height, the young wood being headed in to two or three eyes. The Vines commence bearing the third year from cuttings, and come into full bearing between the fourth and sixth years. No training is needed except the placing of an occasional prop under the heavier fruit-bearing branches.

The vine is grown almost exclusively on the hippurite limestone about Smyrna, up to a height of about 400 feet above the sea. This consists of a white "brashy" rock, intermixed on the weathered surface with stiff, ochre-coloured loam. The ground is prepared by trenching from 2 to 3 feet deep; the larger rocks are either carried away or used for boundary walls, the smaller "brash" placed in the bottom, and the loam intermixed with small stones got to the surface. The vine shoots, after developing the bunches of fruit, are pinched-in in May, which produces a secondary growth and a rather later crop of smaller fruit. The small, useless shoots are pruned out during the summer, but there is no other pruning till the ripe wood is headed in to two or three eyes in the winter. The soil is bared from the roots, and heaped up in the late autumn, and a dressing of goat or horse manure applied every other year. The soil is levelled down again in January.

The harvest commences about the middle of July, and occupies about a month, the fruit from the laterals succeeding that on the main shoots. The bunches, on being gathered, are dipped in a solution of wood-ashes to which a little oil has been added. This is said to assist and expedite the drying, which is done on the ground, and occupies from three to six or seven days, after which the fruit is shaken off and packed in drums.

The Sultana does not seem to have suffered so severely from the oidium (= *balyk*, Turkish) as the Patras Currant, and it is also said to be less liable to attack than the Muscatel vine. The disease seems to be dying out, its virulence is said to be arrested by severe winters, but it has been noticed that a long succession of southerly winds develop the attack. An

application of sulphur as a preventive is made when the lateral shoots are about an inch long, and again when the fruit is forming.

Most of the vineyards are in the hands of small proprietors; some are absolute freeholds, and others are held under various forms of tenure. They are not found remunerative as an investment when carried on with paid labour, and for the most part they merely serve as a sort of small savings bank for the spare labour of the working people.

As a crop Sultanias are eminently speculative, the produce fluctuating with the season and the price also with the crop, and after two or three productive years the value falls below a remunerative rate. They are more costly to cultivate than Currants, and cannot compete with them at equivalent values for general consumption. The demand is therefore limited at remunerative rates. A few years ago an excessive production so lowered the price as to lead to the rooting up of a great extent of the vineyards. This was carried to excess, and was followed by a reactionary rise in price, which has induced replanting.

The present production of the Smyrna district is about 10,000 tons per annum, and a few are also grown in the neighbourhood of Patras, but the present local price of from 25s. to 35s. per cwt. is not looked upon as remunerative. An acre contains about 2000 vines, and the produce of dry Sultanias varies from 7 cwt. up to 30 cwt. per acre, in some cases rather more. In common with the other agricultural crops of Turkey the Sultana is subject to a local tithe of from 10 to 12 per cent. on the value of the crop as it stands, and the only other fiscal charge is an *ad valorem* duty of 1 per cent. on export. *George Maw, F.L.S., Benthall Hall, Broseley.*

MR. CANNELL'S NURSERY.

MR. CANNELL'S nursery at Swanley, in Kent, promises to be one of the most important manufacturing of soft-wooded plants in the country. It is

FIG. 81.—PACKET-POST PLANT CASE.

most conveniently situated close to the Swanley Junction of the London, Chatham, and Dover Railway, and a siding runs into the nursery. The ground, which is about 17 acres in extent, forms two slopes facing respectively north-west and south-east, abutting against the high railway embankment, which forms a most welcome shelter and shade on the south-west.

In the valley between the slopes Mr. Cannell has commenced building his glass-houses, of which some half a dozen, with steep span-roofs, and each 100 feet long, are built so close together that an asphalted pathway, level with the wall-plate, has been made between each house; these are found to afford much facility for painting, repairs, shading, &c., and also forms gutters to conduct the roof-water into capacious tanks which extend beneath the party walls from the pathway inside one house to that within the next adjoining. The houses are of plain and simple construction, but well suited for growing small stock, in which Mr. Cannell principally works, and plants do extremely well in them in consequence of the great amount of light to which they are exposed. In houses of this description it is very common to see the wall-plates and lower parts of the sashes speedily rotting away, while the upper parts remain quite sound. Mr. Cannell prevents this by painting this lower portion of the woodwork with pitch, which must act very efficiently as a preservative, and does no harm whatever to the plants which cannot be obviated by a subsequent coating of whitewash. Adjoining these houses are eight 100-foot lengths of heated pits, each

warmed by a circuit of pipes placed up close to the glass, "to keep the frost from getting in," as Mr. Cannell puts it, and intended also to keep the atmosphere dry and comfortable during winter. In these pits the stock of greenhouse plants of all kinds, as Cyclamens, Cinerarias, Pelargoniums, Chinese Primroses, and hosts of other popular flowers are housed; while in some, by the aid of this heat, the plants are kept growing on and blossoming all through the winter, furnishing useful supplies of cut flowers. Pelargoniums, Fuchsias, and Petunias are prominent amongst the contents of the glass-houses, and we also saw some neatly grown well bloomed Achimenes and Lantanas, *A. longiflora* major amongst the former, being particularly telling.

The intention is to build a similar set of houses on the opposite side of a central pathway, and to connect these by an enclosed and heated covered way, adapted also for the growth of larger plants, and leading from a seed-shop at the roadside, so that all the glass-houses can be reached and traversed without exposure to the weather. Mr. Cannell is a man of energy, and we have no doubt that, if favoured by fortune, this expansive idea will be carried out. The heating is, of course, done by the Victoria Circulator, which is said to be found very efficient.

The whole of the ground is not yet brought into nursery cultivation, and some of that which is broken up is not filled with flowers, but as fast as it can be done—and forming a nursery of choice flowers out of an open cornfield is no easy work—quarter after quarter is filled, and in the height of the season this display must remind one somewhat of the blaze of blossoms seen in Messrs. Carter & Co.'s annual grounds, or in Mr. Waterer's acres of Rhododendrons and Azaleas. Pelargoniums were in grand flower in the open beds at the time of our visit, so were Phloxes, Lobelias, Calceolarias, Dahlias, Gladioli, Pansies, and other popular subjects, the display of the former being then the most attractive. A bed of the Bluebell *Viola* was also a perfect sheet of rich bluish-purple; this variety had stood through the hot dry weather of June, and was still gorgeous, more than a match for the Purple King *Verbena*, now that *Verbenas* have become so fickle of habit.

A fine collection of Chrysanthemums is cultivated at Swanley, and a sloping bank of considerable extent is devoted to a collection of permanent plants of some 400 sorts, which are grown in order that purchasers may, if the season permits, see them in flower. Some varieties of the dwarf early-blooming race we found in full bloom, and these would be very useful in many gardens, if grown for mid-season plants, to plunge in the place of any subjects which might be going off. Of these we particularly noted *Madame Damage*, which grows about 1 foot high and produces a dense mass of flower-heads, which are of medium size, and a bright pale yellow colour; *Scarlet Gem*, of similar habit, has flower heads of a bronzy red colour; *Madame Piccol* is a purplish-rose; and *Perpetual-flowered White* is a pleasing blush variety. These are all desirable plants from the point of view just indicated.

Among the Pelargoniums which were particularly fine the following may be mentioned:—*Arago*, with bright green zonate leaves, and very large close trusses of finely shaped large pale cerise-scarlet flowers, in the way of Cannell's Dwarf, but superior to it; *Didon*, with bright green zonate leaves, and finely formed large orange-scarlet flowers in bold trusses; *John Gibbons*, plain green leaves, and very large brilliant glowing scarlet flowers, of large size and fine form; *Rev. A. Atkinson*, with zonate leaves of a dull darkish green, and very large, finely-shaped flowers of a rich glowing crimson-scarlet. *Vanessa*, a fine salmon, with a flush of rose, was very beautiful, the trusses being fine and abundant, and the colour distinct and striking; the leaf is dull green and zonate; singularly enough this variety met with no acceptance in the Chiswick trials. *White Clipper* was one of the best whites, and *Snowdon* was also flowering well. *Master Christine* was decidedly the most floriferous and effective of the pinks. *Nemesis*, a very strong grower with zonate leaves, had immense trusses of large bright scarlet very richly coloured flowers; the trusses have some of them measured as much as 8 inches across, and no doubt it is one of the finest of the large-growing varieties. *Mrs. Turner* produces splendid trusses of the brightest pink. Amongst the doubles *Madame Thibaut*, one of the rosy pinks, is a remarkably free bloomer, both indoors and out, and may be con-

sidered as one of the very best. Eugène Bandouin was another meritorious pink, but having a flash of deeper red than Madame Thibaut.

A few other outdoor subjects which particularly struck us as worthy of notice were *Calceolaria Little Beauty*, a variety of herbaceous habit, with arachnoid leaves and a corymbose inflorescence of very rich dark velvety maroon flowers, almost black; a very rich looking variety. *Lobelia Brighton* was the best of all the bedding sorts, bright blue, compact, and dwarf in habit; none of the others approached this for effectiveness. *Defiance* is a variety of a reddish purple hue, too deep to call a lilac, very compact in growth and free, and the best by far of this rosy tint which has come under our notice. Another good subject for hardy bedding arrangements is the *Cineraria ceratophylla*, a plant in the way of the old Dusty Miller, *Cineraria maritima*, but more compact in habit, and much more elegant in appearance from the leaves being more finely divided.

In the houses a great blaze was still made with Zonal Pelargoniums, although these were past their best. Mr. Cannell is, however, determined to have a supply of flowers through the winter, and for this purpose a set of plants are under training. The fine varieties here grown are far too numerous to mention. We may, however, refer to M. Sisley's fine novelty, named Dr. Denny, one of the most lovely varieties yet raised, in which the lower petals are of a rich glowing magenta, and the two upper ones have each a distinct blotch of scarlet on the lower half, producing a wondrously rich effect. A salmon-coloured variety, *Lady Eva Campbell*, is far in advance in its colour, and a most lovely pot-plant; unfortunately few of the varieties of this colour do well in the open beds, at least about London, though both these and the scarlets appear to flower better in the calcareous loam and pure air of Swanley. *New Life* was flowering very freely, and proving quite constant to its striped colouration; in growth and free-flowering properties it is the exact counterpart of *Vesuvius*, from which, like *Wonderful*, it is a sport.

Fuchsias were rather past their best, but enough remained to show that *Bland's Striped*, with a much expanded purple and rose corolla, was a very showy sort; that *Father Ignatius* and *Model* amongst the sorts with purple corollas; *Black Prince*, with a rosy corolla; and *Cannell's Gem* and *Covent Garden White*, amongst those with white tubes and sepals, were some of the best and most useful decorative sorts. *Aurora superba*, salmon coloured, with orange-red corolla, the flower showing a decided flush of yellow, is also a very striking variety.

We noticed a charming variety of *Lantana* named *Pluie d'Or* among the novelties of the season. This will be sure to be a favourite with cultivators, as it is of the fine habit of *L. crocea*, with deep orange-yellow flowers of a pure clear unchanging colour, very rich looking in tint and tone. *Ageratum Lady Jane*, also new, is the best of its group, being of a better colour with fuller flowers than its rivals. *Coleus multicolor* is a plant to be looked after; it has small deeply-cut leaves, which are blotched in a varying manner with pink and bronze.

The millions of seedling plants of such subjects as Chinese *Primulas*, *Calceolarias*, *Cyclamens*, &c., raised here are quite bewildering, but Mr. Cannell does an extensive business amongst these small subjects through the post-office, the demand not being limited to this country, but extending to the Continent, to America, and to India. Those for India are sent out in very simple but very efficient plant cases, of which the annexed sketch (fig. 81, p. 405) is a representation. It consists of a deal box 2 feet by 1 foot, one-third of the lid being of rough plate glass, fastened down with india-rubber, and the whole protected with wooden bars, so that the box can be tossed about without it or its contents sustaining any damage.

Home Correspondence.

Lilium cordifolium.—Mr. Fitch describes the New plant as having "leaves commencing a few inches from the ground, gradually decreasing in size upwards till they pass into bracts." The dried remains of its stem are now before me, and in my judgment they quite confirm Mr. Max Leichtlin's statements. The entire height of the stem is 26 inches. The first fully developed leaf-scar is exactly 12 inches from the base of the stem, and is about half an inch broad. Six inches below this is a small round

scar about $\frac{1}{2}$ inch broad, which may have given origin to a very small leaf, which must soon have withered. In the 4 inches above the second well-developed scar are crowded the insertion of no less than six leaves. This exactly agrees with Mr. Max Leichtlin's statement that "the stalk is not leafy, but rises bare to the height of 1 to 2 feet, and then six to eight leaves appear in a sort of rosette. The following are exact measurements of the *Kew* specimen:—1st leaf (?), 6 in.; 2d leaf, 12 in.; 3d leaf, 14 in.; 4th leaf, 15 in.; 5th leaf, 15 $\frac{1}{2}$ in.; 6th, 16 $\frac{1}{2}$ in.; 7th leaf, 17 $\frac{1}{2}$ in.; 8th leaf, 18 in.; 9th leaf, 19 in.; 1st flower, 20 in. *W. T. Thiselton Dyer*.

Roses in Autumn.—

"There grows a bonnie Brier bush
In oor kaleyard."

Towering through a hole in my greenhouse is a *Marchal Niel* Rose crowded with flowers, and the arches of the kaleyard are radiant with Rose blossoms. *P. Barr*.

Names of English Plants.—The reference to the origin and spelling of the name of the *Woodruffe*, alluded to in Mr. Tuckwell's pleasant article in the *Gardeners' Chronicle*, September 22, p. 363, has recalled to my mind a jingling rhyme in which the ancient spelling of the name is given, and which your contemporary, *Nature*, of last week, has given in an incorrect form. It is as follows:—

"Double u, double o, double d, e,
R, o, double u, double f, e;

i. e., *Woodruffe*. Does not this orthography militate against the derivation from *roue*, which has been suggested? *I. O. Westwood, Oxford, Sept. 23.*

The International Potato Show.—I beg permission to say that a truly "international" character will be given to the third annual Potato exhibition, to be held next week, inasmuch as that enterprising firm, the Messrs. Bliss, of New York, are sending a large number of dishes of tubers for competition in several classes. This will be the first opportunity offered to home growers to compare American exhibition samples with those of their own production. I am authorised to say that in consequence of strong representations having been made to the committee by their trade supporters generally, the obnoxious practice of fixing numbers of large cards to various dishes of Potatoes in all parts of the show, stating that these were grown from seed supplied by such a firm will be rigorously put down; a resolution having been passed empowering the officials to at once remove any such placards. The promoters are desirous that the exhibition should be made the medium solely of promoting the cultivation of and popularising the Potato, and not that it should degenerate into a mere advertising medium. In spite of the great prevalence of the Potato disease it is very satisfactory to hear from many directions that a fine representative collection of tubers is expected, and there is no present indication of any falling off either in quality or quantity. *One of the Committee.*

Strawberries.—On reading my friend Mr. Harrison Weir's remarks (p. 373) on his short crop from *Vicomtesse Héricart de Thury* it struck me that our experience was the reverse of his, so I asked the gardener which *Strawberry* bore best this year; his answer was "The *Vicomtesse*—it usually does." The name puzzles some gardeners; a neighbour lately told me that his gardener thought highly of "Count *Harcourt*"—not a very bad shot. *George F. Wilson, Heatherbank, Weybridge.*

Pumpkin Preserve.—The partial failure of the Apple crop, and the great scarcity of Plums and other fruit suitable for making preserves to use during the winter, is a source of concern to many, and they will therefore be glad to learn that they may fill their jam-pots with an excellent substitute made from the Mammoth Gourd or any ripe Vegetable Marrows. The former, however, is greatly to be preferred on account of being more fruity and the flesh of a much better colour, equalling in the latter respect that of the Apricot, with which it is said to be used largely for the purpose of adulteration. For the past three years, Pumpkin preserve has been one of the principal sweets used in my house, and is greatly relished by us all, so much so that I would rather have it to any made from common garden fruit. As an adjunct to boiled rice, or plain puddings made from that grain, it is simply delicious, as it is likewise for tartlets, or indeed any of the many uses to which preserves are put. To make good flavoured jam that will keep, the Pumpkin should be full grown and perfectly mature, a condition they are generally in by the end of September. When quite ripe the skin of the Mammoth Gourd assumes a warm reddish yellow hue, and the flesh when cut into is almost as solid as a Swede Turnip, to the

colour and texture of which it bears a close resemblance. In preparing the fruit for preserving, it should be cut up into thick slices for the purpose of being peeled, and after that is done and any soft spongy part in which the seed is embedded taken away, the solid portion remaining should then be cut in square pieces about the size of dice and weighed. To every pound of the Pumpkin add three-quarters of a pound of lump sugar, and for flavouring divide either an Orange or a Lemon and boil together for from one hour to an hour and a half to evaporate the watery matter and get the jam to stiffen properly, keeping well stirred to prevent it sticking to the bottom and becoming burnt, which from the time it has to boil it is liable to do. One Orange or a Lemon is sufficient for 5 or 6 lb. of fruit; but more or less may be used according to taste, or a few drops of essence of ginger or any other flavouring matter that happens to suit the palates of those likely to consume it. In using either Oranges or Lemons, they should simply be cut in halves, that they may readily be taken out before putting the preserve in jars; otherwise, if mixed up in it, the rind is too strong to be pleasant. Considering the great ease with which Pumpkins may be grown in positions that are quite useless for other purposes, and their exceeding value when, in seasons like the present, other fruits are not to be had, the wonder is that their merits have been so long overlooked; for, except in cottage gardens, it is very rare they are seen, and even there, those cultivated are of little value compared with the Mammoth Gourd, which is not only large and handsome, but is very superior to any of the others. There are few places that have not offensive-looking rubbish-heaps or unsightly objects of some kind or other to hide, and this cannot be done in a more profitable way than by covering it with the fast-growing bine and handsome foliage of this noble-looking Pumpkin, the fruit of which, from its rich colour and enormous size, is very striking and sure to attract notice. The largest I ever saw was grown on a heap of garden refuse containing a quantity of decomposing stumps of Broccoli, the mowings of grass from the lawn, weeds, and other gatherings that, from the large bulk they formed, generated a gentle and lasting heat which just suited the plants, as they grew with great rapidity and set fruit early; and as there was never any lack of moisture in this mass of vegetable matter they were not checked in their swelling, the rate of which was astonishing and could be noted from day to day. It is not long since that *Rhubarb* was little cared for and could scarcely be sold at any price, but now it is looked on as indispensable and one of the most wholesome and profitable garden products grown. If the public once find out the value of Pumpkins as an article of diet during the winter, either for using in soups, pies, or as a preserve, the demand is sure to be great, and it may therefore be worth while for those who have waste places, such as the roofs of sheds or piggeries, to grow plants over them, which will serve as shade and add handsomely to the market returns, in which, unfortunately for fruit growers, there has this year been a sad falling off. *S. W.*

The Golden Queen Grape at the Crystal Palace Show.—In the *Gardeners' Chronicle* for the week ending September 1 of the current year, the following announcement appeared, namely:—"The prizes of £5, £2 and £1, offered by J. K. Pearson, of Chilwell, for the best single bunch of his new Grape, *Golden Queen*, will be competed for at the Crystal Palace Show, September 21 and 22. The awards will be made by the Crystal Palace judges." This notification induced me, "amongst others," to send to the above-named show the best and ripest bunch of this kind of Grape which I possessed. To my surprise, on the return of my representative from the show he handed me a card on which was written, "Prizes withheld: not in sufficiently good condition." As I understand the advertisement, no special conditions are stipulated; and, therefore, I hold that it was an act of injustice to withhold such prizes, unless the donor of them had made some reservation, which has not been published. I should like to know if this be so through the medium of this publication, because others, like myself, are interested. *G. T. Miles, Wycombe Abbey.*

Fungus Attacking Wellingtonias.—At a place that I am arranging in Sussex we took for a portion of the pleasure-ground a site which had previously been covered with large timber trees. These, however, had been cut down for some years—*i. e.*, sawn off at the surface of the ground, but the stumps had not been grubbed up. This was, however, done in the preparation of the ground, and all the large roots extracted. Beech was the principal timber tree previously grown upon the land. The soil is a very light sandy loam, of a dark colour, and with a goodly smattering of ironstone in it. On a flat portion of this ground we planted an avenue of trees, consisting of *Wellingtonia gigantea* and *Abies Nordmanniana*, placed alternately. Previous to planting the ground

was well trenced to a diameter of 12 feet and 2 feet 6 inches deep for every tree, and every vestige of the old roots was carefully removed, a good quantity of fresh soil being mixed with the old. The trees were then planted, and have grown vigorously for two successive seasons, some of them being now from 8 feet to 10 feet high, and exhibiting the rudest health. But alas! this state of things was not long to continue; three or four of the Wellingtonias began to show a sickly appearance, and on my attention being drawn to it, I examined them, and on removing a portion of the earth I found the stem close to the ground covered with the mycelium of some fungus. I had one of the worst affected dug up, and found that all the old roots were more or less affected in the same manner as the stem, although I did not observe any trace of it in the soil, and the young roots appeared quite healthy. The stem was affected all round, and to about 6 inches in height. Knowing that such cases had occurred before after planting young trees on the site of old plantations I was doubly careful in removing the old roots and preparing for the new trees. The Abies Nordmanniana is not at all affected, and all kinds of trees and shrubs usual in a pleasure-ground have been planted on the site, about 7 acres in extent, and are in a thriving state, not a single plant having been found to be affected with the fungus excepting the Wellingtonias. We have many fine Wellingtonias not yet affected, or at least showing no signs of it, although they are all undergoing a careful examination. I shall be glad if you will print this, in the hope that some of your many readers may have had similar experience, and found out an effectual remedy. *George Eyles.*

Tritonia Macowani.—Herr Max Leichtlio's statement (recorded by Mr. Barr in the *Gardeners' Chronicle*, p. 374) respecting the hardness of this plant is indisputable. We have it now blooming freely, with vigorous growth, having been planted out in a rather flat bed more than twelve months. The height of the scape is from 1½ to 2 feet. It is a most desirable species. *Wm. Rollisson & Sons, The Nurseries, Tooting.*

— Mr. Barr's note respecting the decorative value of this comparatively new hardy plant is timely, as those who may wish to possess it can now see it in flower. A recent figure of the flower gives a very poor idea of the size of the spike, and its form and beauty, as in the plate the flower is represented almost as an inverted cone, whereas it is really the reverse, and differs but slightly from the spikes of that well-known kind, *Tritonia Uvaria*. Here *T. Macowani* is doing well in the open ground; small bulbs, having thrown up flowers in the summer, have now fine heads of bloom, and a third is just coming up. I think it will prove as hardy as *Uvaria*, and when clumps are well established not much less robust. It will make a charming border plant, and the hue of colour of the flowers, it less striking than is that of *T. Uvaria*, is softer and far more pleasing. *A. Dean, Bedford.*

— I am glad that Mr. Barr has called attention (p. 374) to this beautiful plant, one of the early specimens, introduced by Mr. Green, has been in our rockwork for more than two years. It is now in bloom and much admired. The delicacy of its colour and its size and shape adapt it for situations unsuited for the grand old red-hot poker. *George F. Wilson, Heatherbank, Weybridge.*

Pinning Dahlias.—Referring to your remarks upon the *Dahlia Baron Tauouat* at the Alexandra Palace, permit me to correct two errors. First, you infer it was in the class for forty-eight, open; on the contrary, it was in my 1st prize stand of twenty-four, amateur. Second, you say "a pin was put through the eye to lengthen the stem." I now send you a counterpart of the wire used for the stem, and beg to say the pin story is without foundation. I need hardly add it is the common practice to mount blooms that break off on wooden pegs, and I have simply adopted wire through the natural stem instead. The judges only required momentarily to examine the flower after their attention had been drawn to it by (I believe) a less fortunate exhibitor, and their "anxiety" was of the shortest duration. *S. Dobrée, The Priory, Wellington, Somerset.* [By the term "pin" our reporter meant the piece of wire used to mount the bloom broken from the stem, and as on examination it proved to be longer than the severed stem of the flower, the remark was correct in point of fact. The difference in the phraseology is of but small moment. The head of the wire in the centre of the flower had the appearance of that of a pin, and it was distinctly visible to the eye, and the attention of the judges was properly called to its presence. *Eds.*]

Colchicums.—At the present time, as Colchicums are—"all a-growing and a-blowing"—it may interest your readers to know something of this charming autumn flower, which is at present far less frequently met with than formerly in flower-gardens. The fresh,

rich, bright colours of the Colchicum may be seen nestling in herbaceous borders, in semi-wild situations, or from amidst grass, at a season of the year when "coming events cast their shadows before" in the shape of heavy dews and frosty nights, disfiguring the Pelargonium, and making all in the summer flower garden look unhappy—these, with the early-flowering *Crocus*, the *Zephyranthes*, *Tritomas*, *Sternbergias*, &c., under the same influences, are uninjured, and form a truly charming autumn flower garden. The noblest of the Colchicum family is *speciosum*, of which there are two varieties—the lesser with a rose-pink flower, and the greater of a rose-magenta colour and conspicuous white centre. This latter is simply grand. The next, lower in the scale, but still noble, and characterised by its great floriferousness, is *C. byzantium* and its variety *longipetalum*, with bright rose-coloured flowers, forming a perfect carpet of colour. The variegated foliage variety of *C. byzantium* produces small white flowers. The third grade down is *C. autumnale*, a species found growing abundantly in the meadows in various parts of this country; the roots are sent to London, and are largely used in medicine. The type which is found in the meadows has a rose-purple blossom. The varieties which are less common are the white, the rose, the striped, and the very pale variety. Besides these single forms, there are three doubles—a purple, a purple striped white, and a pure white. *Variegatum* ranks fourth, the flowers are beautifully tessellated, rose-purple and white. Of this there is a beautiful pale variety, while *Parkinsoni* is a near ally. The foregoing embrace the more decorative species and varieties. *C. letum* has small pale rose flowers; *montanum* rich rose-lilac blossoms. Besides these there are a few others, but we fear the names only are known in this country, the plants not being in cultivation. *P. Barr.*

Gladioli Reverting Back.—I am curious to know whether any other readers of the *Gardeners' Chronicle* can confirm my experience with respect to Gladioli. In the light sandy soil of Weybridge Heath I find that both *G. brencleyensis* and the choicer varieties revert to *gandavensis*. For a long time I could not believe this, but supposed that repeated mistakes had been made in replanting them; I am now, however, convinced of the fact. *E. H.*

Protecting Trees from Rabbits.—I notice an inquiry and a recommendation or two about protecting trees from rabbits. I believe the very best of ways is to tie a small bundle of dead branches round the part to be protected, and trees in hedgerows or where they would be cropped by cattle and horses, can be protected in the same way—any cuttings from hedges, &c., will answer. To prevent deer and stock from barking exposed young trees, the same remedy is applicable. *W. A. Wooler, Sadberge Hall, Darlington.*

Stramonium, otherwise Thorn-Apple (Datura Stramonium).—I was acquainted with the medicinal qualities of this remarkable herb early in life, for some fifty years ago my uncle smoked Stramonium and swallowed the smoke, which enabled him to cough, and thus cleared his throat, after which he could go about his work without suffering any inconvenience. This was no quackery, but an effectual remedy for a deadly complaint, since it is just as easy to kill a man by want of breath as it is by want of food. We find this plant frequenting rubbish heaps and waste ground, and in old gardens somehow or other it crops up just as Goldsmith has it—

"Near yonder copse, where once a garden smiled,
And still where many a garden flower grows wild."

Not only do we find this plant of little repute in our gardens, but most people treat it as a weed. When we go into its history we find it in very doubtful company, for it belongs to the natural order Solanaceae, and berded with Henbane, Tobacco, deadly Nightshade, and Mandrake. When we turn to the opinion formed by our forefathers regarding the Thorn-Apple characterised by the superlative *spitiosissima*, if it have only half the evil properties ascribed to it in ancient Herbs, it should be cast forth bag and baggage. The whole of the plant is said to be powerfully narcotic, but especially so in its fruit and seeds; and according to Tournefort, the King of France's botanist, 1718, a decoction of them drives people mad, and may be used as a poisonous drug by thieves to stupefy those they intend to rob. Now we find many confirmed tobacco smokers declare that some high medical authority advised them to try a gentle whiff of "the weed" just to clear their throats; but as I have been more than once snubbed for speaking disrespectfully of the smoke traffic I shall not wilfully add to my former failings, although it is not easy to keep one's temper when you see a man starving for food and clothes, and yet buying smoke at a high figure with the money given him to get the real necessities of life. I fear the Thorn-Apple is not alone in its powers of depriving people of their senses,

for the family connections above named are strangely mixed—some stinking, vile, and deadly, others good for food, and many of them exceedingly beautiful. At all events the Stramonium has one virtue which I have named, and I am not indebted to any authorities for what I have stated. I do not see the smoke theory stated in books on medicinal herbs, and what I know of this sturdy herb is practical information—I learnt it when a child. *Alex. Forsyth.*

Mushrooms for Market.—Mushrooms are largely grown by the Fulham market gardeners, finding a ready market at very remunerative prices. They begin to collect the droppings about the end of July, and continue until nearly Christmas. As the manure comes home all the litter is well shaken out of it, the droppings thrown up in long ridges and kept regularly turned, so as to prevent over-heating, and the straw is stacked till it is required to cover up the beds. They begin to make the beds about the first week in September and continue until January. Some growers have several acres covered with beds. The ground is marked off into 2½ feet beds, with spaces 5 feet wide between them; there is 3 inches of soil thrown out of the 2½ feet spaces. The droppings are then wheeled in and built into a ridge 2½ feet high, heating them as firmly as possible as the building progresses. After standing a few days, until they get to a heat of about 60°, they are spawned and again well beaten all over, and covered with 2 inches of soil, which is firmly beaten down and covered with a few inches of straw. As the weather gets colder this is added to and mats thrown over it; if the weather gets very severe more straw is thrown over the mats. The Mushrooms are ready to gather in five or six weeks from the time of spawning. A ridge 20 yards long will produce about 10 bushels per week, and they last for about two months. The spawn is used in much larger pieces than I was prepared to expect. Their cakes are about 12 inches square, and they are broken into four pieces, sometimes into six, but the four are preferred. These are placed in the beds on the flat side at 1 foot apart. They attribute much of their success to the large size of the pieces of spawn. I would call the attention of growers with Mushroom-houses to be careful not to use over-dry soil; it is generally dry loam that is used in private establishments for covering the beds, and kept in that state of dryness that the Mushrooms are in a semi-dried leathery state, without flavour or freshness. The market gardener uses the surrounding soil, and there are only a few inches of straw, which helps to retain the moisture, and they gather bushels of fine-flavoured, plump Mushrooms at a gathering off a comparatively small space. Amateurs with an empty outbuilding or shed of any description, from the above remarks may not be afraid to try their success at producing this, the most esteemed of esculents. If they don't want the litter for covering, it is not quite requisite to over-shake the very shortest out of the droppings, only the beds will have to be made a little deeper; and as for maiden loam, it does not appear to be an essential. When these matters are attended to, and the spawn is good, Mushroom-growing is a very simple affair, and nothing can be more simple than the above mode of growing them, and the results are most satisfactory. *E. W.*

Planting Crocuses.—At what depth can I safely plant Crocuses without preventing their vegetating and blooming? My wish is to preserve them from mice. In your journal for 1867, p. 1099, Mr. William Backhouse, Walsingham, by Darlington, writes: "I prefer setting them nearly 6 inches deep, and they are thus in less danger of being eaten by mice." Again, in 1860, p. 1064, the writer of the *Calendar of Operations* writes: "The bulbs should be covered from 2 to 3 inches with fine mould, and not more than 2 inches apart." Again, in 1857, p. 807, Mr. Robert Shackell writes: "If people were to plant their Crocuses deeper than they do in general, they need not be taken up for many years. The hedding plants in summer could be planted on them; 9 or 10 inches are not too deep. They will bloom beautifully planted much deeper than this." To what depth may I safely follow Mr. Shackell's advice? What is the proper time for planting *C. Sieberi* and other winter flowering species? And what for planting *C. nudiflorus*, and the other autumn flowering species? *Diss.* [Plant while the bulbs are dormant. Perhaps some of our correspondents will record their experience of deep planting. *Eds.*]

Engrafting upon Unsuitable Stocks.—The accompanying specimen is a longitudinal section of wood sawn out of the base of the stem of *Libocedrus decurrens*, *alias* *Thuja gigantea*, and is sent to show the unsuitable nature of the stock for the species engrafted upon it, as well as the impropriety of nurserymen attempting to engraft new coniferous trees or shrubs for sale without the knowledge of their proving an ultimate success. Out of six plants of the above-named genus, purchased about nine or ten years ago,

one after the other has died off until they are now all gone. They kept healthy and looked well for some years after planting, but never seemed to get away; the largest never attained a height exceeding 6 feet. There are no doubt many others besides myself who have lost their plants from a similar cause, and may have been attributing the failure to something else. I would advise those who are about to purchase a kindred lot, to examine the plants close to the surface before making a selection, and try and save themselves the annoyance of getting disappointed when the plants are getting established and becoming interesting. *Thuja gigantea* planted at the same time as the *Libocedrus*, under the name of *Thuja Lobbii*, is now close on 30 feet in height; it is quite hardy, and I think will soon take its place as a forest tree. *J. Webster, Gordon Castle.* [The specimen has not reached us, but we print our correspondent's letter all the same, the subject being one of importance to nurserymen and planters. *EDS.*]

The Roseless Autumn.—The Roseless autumn, as described in your columns, has been the same here, in the neighbourhood of Crowthorne, Berks. None of the autumn Roses bloomed to any perfection in comparison to what they have done in former years, and those few that did bloom had to struggle for a precarious existence, the trees and leaves being black or yellow, looking all the same as if they were struck by lightning. The blooms that did come were of a dingy colour. The summer Roses did not do well either; all my trees suffered severely from the cold winds last spring and the late frosts. The only kinds that did any good were Céline Forestier, Noisette; Gloire de Dijon, Madame Margottin, Teas; Charles Lefebvre, Marquis de Castellane, John Hopper, Eugène Appert, Hybrid Perpetuals. In conclusion, I may state that the soil is sandy and dry, and soon gets dried up. *A. H. H.*

Gladioli at the Langport Nurseries.—When I visited these nurseries on September 17, I found a glorious display of these noble autumn flowers far surpassing anything I had ever seen before. You may judge what a display of flowers there is when I say there are 4 acres of flowering bulbs, besides 2 acres more of seedling and stock roots. The whole collection is cultivated in a superior manner, and if any of your readers can find it convenient to go there at once I can promise them a rich treat, even thus late in the year, but of course the last week in August is the proper time to go there to see them at their best. I saw many splendid new flowers which are to be sent out next spring, and those that have been sent out during the last few years are to be seen in the best possible condition. There are no fewer than 270 sorts cultivated there. The exhibition roots grown for the present year number at least 4000, and Mr. Kelway reckons that after the whole available bulbs for this year's sale are taken out, he shall have seedling and other named stock roots to plant 20 acres of ground 6 inches by 3 apart. Spikes of Gladioli for decoration are sent to all parts of the country from this nursery. On the day of my visit 500 spikes were cut to send away, and when I looked over the beds again you could not miss them. After September 1 the average number of spikes cut and sent to different parts of the country for decorations is 2000 per week. In the seed-beds there are not less than 20,000 seedlings, besides the named kinds increased from spawn. Besides the grounds, there are the store-rooms, packing-room, all neatly fitted up, and heated with hot water, all worthy of inspecting, and a spacious drying shed at one end of the nursery is about to be heated as well. *J. Clarke.*

The Prickly Pear.—Is the Prickly Pear, mentioned in the *Gardeners' Chronicle* of the 22d as having become a pest in the Indian forests, the same plant as the Indian Fig, the Cactus *Opuntia*? [Yes.] If so, the fruit is very agreeable, and sugar has been made from it in Sicily. The Mexicans prepare a cooling drink, called *colindre*, from it, and the French in various parts of America make very pretty ornamental vases and flower-trays out of the network found in its stems. I have often eaten the fruit in America, and an American gentleman, a good botanist, told me that he had seen the plant growing in lava at the foot of Mount Etna when he visited Europe. The Indians of Florida used to live upon its fruit for three months in the year, and settlers in California think it is invaluable as a fence. They plant three rows of it close together, and defy any mortal animal to break through it. *Helena E. Watney, Liss.*

Potash for Vines.—Acting upon the suggestions offered at p. 338 with regard to the use of potash for Vines, I determined to put the same into practice, and therefore obtained from the druggists a small quantity of the said article, and selected two Vines growing in pots, but not fully ripened (being eyes of this season's growth), the one variety being Mrs. Pince, the other Black Hamburg. I then, with the use of a pocket-

knife, placed about equal proportions upon the surface of the soil, leaving the same to be absorbed by the earth, and so mingled with the roots of the Vines. The operation being completed, I directed that no one should be permitted to meddle with them. I visited them myself daily, but on the third day after the application of the potash, to my great surprise I found the leaves of both varieties drooping and dying, the stems having turned quite black. I would, therefore, recommend all intending experimenters to take a warning from my sad experience, and not to try the use of potash with Vines, unless they wish to meet with similar losses. *Vitis.*

Colchicum speciosum rubrum.—Now that Colchicums are in bloom, I thought it would interest you to see my *Colchicum speciosum rubrum*, the species figured in the *Botanical Magazine* some years since from my plant. The ordinary *speciosum* is smaller, and as pale in colour as *C. byzantinum*. *P. Barr.*

WEEDS.

It is very nice to live in the country, and have a garden, and be able to grow one's own flowers, if not one's own fruit and vegetables, but there are some serious drawbacks to this delightful state of things, for there is at times a good deal of light work—ay, and very often a good deal of heavy work—to be done in a garden. The ground will not be idle. If we do not crop it in season, it will assuredly crop itself, and that in such a way that we may have to remove a heavy swathe of weeds before we can till the soil for a crop. The lawn grass, despite its being gone over once a-week with the mowing-machine, will be thronged with the bright-eyed Daisy flowers and the golden Dandelion, whose handsome yellow heads it seems a pity to cut off. The *Poa annua* is a contemptible little grass, but I have known it rise from seed, and in the course of a month or six weeks grow flower and ripen seed, and make a length of gravel walks and roads quite green after a few wet days. These, however, are only the small fry, the weak weeds that, like the gnats, make up by their numbers for what they lack in power. We have occasionally to deal with weeds well armed, such as Thistles of sorts, and Nettles among herbaceous plants, and such as Gorse and Brambles among ligneous ones.

Sir Joseph Banks, I think, defined a weed to be merely a plant out of its proper place, and as there is so much of this there is nothing for it but weeding. Cheap labour must be had—boys or women must be employed—but this class as a rule think little and care less how the work is done; and therefore, without close supervision, serious loss may ensue, for one has perhaps pulled up all the shabby-looking seed-leaves of your *Mignonette*, leaving some sturdy weed in its place; and another, seeing nothing worth notice in the Parsley-bed, has made fallow ground of that, for this potherb has had the reputation of visiting Lucifer before it appears above-ground. Therefore, as the doctrine of knowing weeds is nowhere taught in our best Board Schools, the country amateur has to run the risk of boys and girls blundering.

The Thistle is a princely weed. We see the Scotch Thistle a yard across and 2 yards high, but the common Thistle lords it over smaller herbs, literally conveying its seed "where winds can carry and where waves can roll." In many situations in Australia the Thistle is a formidable opponent to all progress, and when you have cleared your own holding it may be seeded anew from fields a mile off, for the Thistle seed is attached to a beautiful car so light that the smallest gust of wind will be sufficient to waft it through the air.

Docks have to be pulled up, for they must not be either cut off or allowed to go to seed. Crowfoot usually gets into flower before its companions in the grassfield can shoot ahead; this is the "sit sicker" of the North (sit secure), and it is worthy of its name, for it can hardly be weeded out. The wild Mustard is never wanting, for whatever earth you take Mustard seeds seem to be always in it. Little is known of its mode of life; it may, for aught we know, hibernate like our badgers, or sleep for an odd hundred or even a thousand years at a stretch, or it may rise a new creation, or be evolved from something sharper than itself. We see hundreds of acres of corn-land clad in golden array with this trampy weed, just as if it were the main crop, and the humble cereal was only there on sufferance.

But my present business is not to enumerate or

describe the weeds of either the garden or the farm, but to state some of the preventives against their making headway. A certain lawyer, if I remember rightly, had been, like many others, annoyed with seedling weeds among his field Carrots, and the weeds grew rank and strong, whilst the seed-leaves of the Carrot were small and weakly; so he made it his business to change this state of things, and did everything necessary for the Carrot ridges except sowing the seed, and when the weeds had sprung up as usual he horse-hoed the drills, and thus destroyed every seedling weed at little cost, and then sowed his Carrots.

Mr. Fleming, late gardener at Trentham, was tormented with weeds on his gravel walks, and he invented a machine for poisoning them by watering the walks with scalding brine. Most gardeners have used dry salt to kill weeds, but when used in the form of brine its action is more immediate, and when to this we add the scalding process death is certain, and there is a great saving of labour. A gardener of my acquaintance—always short-handed, as most gardeners are—had to weed the walks and carriage drive on wet days, when the men could not do other outdoor labour, and they had to protect their heads and shoulders with some kind of waterproof covering, but I think it is high time that this class of weeders should be discontinued.

When the late Bishop of Exeter made his new residence at Bishopstowe, near Torquay, he was anxious to have a nice lawn, and did everything to foster the grass, and after a time he succeeded admirably, but his lordship had to face the evils arising from new groundwork where weeds of long standing had got a firm hold of the soil; and in this case it was the common Coltsfoot that had got so mixed with the soil and so broken into small pieces that it seemed to pervade all the made ground. Now the late Dr. Lindley laid it down as a rule that if we could prevent any plant from forming leaves it must necessarily die out. Acting upon this good advice the Bishop weeded out his first crop of Coltsfoot, but only to be succeeded by a second; so he employed a woman "on the lawn" to cut out the crown of every plant of Coltsfoot as soon as it showed a leaf, and for three summers this woman might be seen on her knees like some witch of the olden time, but she effectually cleared the lawn of this conspicuous weed. When Tobacco was scarce and dear during the war with America confirmed smokers used the leaves of Coltsfoot as a substitute for Tobacco. This famine of snuff and smoke was duly bewailed in measured rhyme, of which I can only remember a snatch:—

"For puffing Meg has broke her pipe,
And Wat has tint his spleenchan;
Poor Kate shot in her sneeshan mull
Last night to boil our brochan,
Since Yankees turned our foes man."

A kitchen garden in good order for cropping may be taken as an example of the doubtful happiness and enjoyment of the garden amateur this wet season. The weeds begin to rise rapidly after rain, and are promptly cut off by the hoe, but the Groundsel is nothing the worse for all this, and its fleshy stalks will root afresh, and it will flower and seed as if nothing had happened. I have found it best in such cases not to hoe but dig, and so the weeds get buried deep enough to rise no more. One may see now (end of August) acres of pasture fields, in Cheshire and elsewhere, of the common Ragwort with its gaudy yellow heads of bloom "unprofitably gay," and it is very remarkable that this coarse weed is almost always in good condition, as if it could extract more from the soil than the grasses, for the pasture is often poor while the Ragwort is rich. Surely such an intruder would pay for the plucking up, for it offends the eye, and is worthy of no consideration; and it has a long leg, tempting the owner to pull it up by. I had to reclaim some land that was beset with Thistles, and knowing from long experience that few plants will rise to the surface if buried 12 inches deep—Horse-radish and some others excepted—I laid one-half of the soil on the top of the other half, and by this means laid bare an alley of some width between each bed, just as if I had had corduroy for my pattern. The Thistles never got through the top soil, but shot up blanched stems and curled in circles, and we found them baffled when we came to examine the ground in autumn, and in the alleys the supply was so beggared by having the soil removed that the Thistles never rallied, and were easily kept under by the hoe; indeed, there is scarcely any class of weeds, however rank and deeply-rooted,

that will stand this bastard trenching, and it has, besides, a healthy action on the crop, since the amount of rain falling on these beds is lessened, and the soil is laid up to meet the sun's rays at the best angle that it is capable of forming—say, at an angle of 45°, or as it is called in railway terms, a slope of 2 to 1. It will easily be seen that this arrangement alters the relative proportions of sun and rain by increasing the effect of the sun and decreasing the amount of rain that is lodged on the beds.

This bedding system was detailed by me some years ago in a pamphlet on the Potato. Every one who has watched our seasons will agree with me that we have, as a rule, too little sunshine and too much rain, but it is possible by this open-drain system to shunt the wet and hold up the earth to the sun; and every little is a gain with these most unmanageable elements, while all the summer long the weeds are easily come at, so that by the second year the land will be a clean fallow.

The system of sowing or planting everything in drills lessens the labour of weeding. We see in the Hop plantations that the plants are set out in lines both ways, so that the horse-hoe can be used from east to west, as well as from north to south, thereby leaving only a small square to be hoed or hand-weeded. Seedling weeds should be destroyed whilst in their seed-leaves, and there is no instance of their ever rising again when hoed thus early. The late Mr. James Barnes, of Bicton, used small goose-necked hoes, some not more than 1 inch broad, and he attacked small weeds with these in flower-pots and in beds, and thus thinned crops as well as weeded them most expeditiously. In the Onion country, Bedfordshire, the seed is sown broadcast, and women weeding the young Onions maul them in a way that would alarm gardeners, but they recover and grow and seed to perfection. There the Onion is at home, and the soil rich with manure and brought to a fine tilth.

The sandy land of Bedfordshire evidently has just what the Onion wants, for we find the Alliums growing wild on the banks of the Thames. It is so with certain classes of weeds; they abound over a substratum of rock, clay, or sand, and are well worth studying, for there is no better criterion by which to judge of the quality of a farm or garden than the appearance of the weeds that have held possession for some time. I once took a field where the principal crop was wild Carrots, about as thick as a stocking needle, and the top a strong smelling poisonous umbel that cattle refused to eat, but when this field had been fattened, cleaned, and brought to a fine tilth, it grew Carrots to perfection in beds such as I have described. *Alex. Forsyth.*

Reports of Societies.

Crystal Palace: Sept. 21 and 22.—The annual autumn show of fruits, flowers, and vegetables was held here on Friday and Saturday last, and we are glad to say that it proved a remarkably good show. Of the choice kinds of fruit the display was good, and fairly extensive, while of hardy fruits, Apples and Figs especially, we have not seen a finer lot brought together here for some considerable time, or even in seasons which have been more propitious, and these in particular have been more plentiful than, unfortunately, is the case this year. Dahlias were in unusually strong force for this late season, and exceedingly fine, especially with the veteran Mr. Keynes. Gladioli and Asters were also well shown, particularly the former, which included a wonderfully good collection of English raised seedlings exhibited by Messrs. Kelway & Son, of Langport. The vegetables shown would have made an exceedingly good exhibition by themselves, they were staged in such abundance and in unexceptionable form. We never before saw the staging at the Crystal Palace so full of good things, but before proceeding to details we should add a word of praise for the admirable arrangements made by Mr. Thomson, upon whom the management of these exhibitions has, we believe, now devolved.

There were only three competitors in the class for twelve dishes of fruit, and the 1st prize was taken by Mr. Coleman, gr. to Earl Somers, Eastnor Castle, who, as at the rival establishment on Muswell Hill, came well to the front in all the classes in which he competed. His collection included, of Grapes, Muscat of Alexandria and Black Hamburg, in grand form as to evenness of size and finish; Black Jamaica, and very good Smooth Cayenne Pines; 2 fine Melons, Barrington Peaches, Figs, Green Gages, Pitmaston Orange Nectarines, and Morello Cherries. The 2d prize collection, which came from Mr. Webb, gr. to

J. H. Manners-Sutton, Esq., Kelham Hall, Newark-on-Trent, included two exceedingly handsome Queen Pines, weighing respectively 5 lb. 12 oz. and 5 lb. 4 oz. Mr. Upjohn, gr. to the Earl of Ellesmere, Worsley Hall, was a good 3d. In a class for six dishes, exclusive of Pines, which one would have thought would have brought about a strong competition, there were only two exhibitors, and nothing was shown by them above ordinary quality. Mr. J. Neighbour, gr. to G. Wythes, Esq., Bickley, Kent, took the 1st prize.

In the next class, which was for two bunches each of ten kinds of Grapes, a large display could not be expected, and, as a matter of fact, only Messrs. H. Lane & Son, Berkhamstead, and Mr. Wildsmith, gr. to Lord Eversley, Heckfield Place, entered the lists, and the prizes went in the order named. Fine examples of Black Prince, Black Hamburg, Muscat of Alexandria, Alicante, Trebbiano, Muscat Hamburg, Gros Colmar, and Bowood Muscat were the distinguishing features in the Messrs. Lane's collection; while Mr. Wildsmith staged Gros Colmar and Foster's Seedling, in fine form; Mrs. Pince's Black Muscat, somewhat small in berry but better coloured than is usually seen this season; White Tokay, Black Hamburg, fine in size but deficient in bloom; Barbarossa, Alicante, Muscat of Alexandria, and Veno's Black Muscat, the sample of the latter having longer berries than the Muscat Hamburg shown by Messrs. Lane, and quite distinct from that variety as shown. The next class, for half the number shown in the former, brought Mr. Woodbridge, gr. to the Duke of Northumberland, Syon House, to the front in the prize list with Madresfield Court, good in bunch and berry and fairly well coloured; Golden Champion, small in bunch but the berries of fine size; Lady Downe's, and Muscat of Alexandria, not large in bunch but of fine quality, and good Alicante. Mr. J. Peed, Roupell Park Nurseries, Norwood, came in a good 2d, and Mr. James Bolton, gr. to W. Spottiswoode, Esq., Combe Bank, Sevenoaks, 3d. The best of nine single dishes of Black Hamburg came from Mr. R. Adams, gr. to the Rev. R. Hudson, Frogmore Hall, near Hertford, good full bunches of fine sized berries, very clean, but wanting in bloom to fully finish them off. Mr. Wildsmith was again a good 2d; and Mr. Coleman 3d, with a smaller sample, but they were jet black, and, as usual with Mr. Coleman's Hamburgs, they carried a splendid bloom. However, Mr. Coleman was not to be denied with his single dish of Muscats, which took precedence in that class over examples, and good ones too, from Messrs. H. Lane & Son, and Mr. John Day, Norton Hall, Daventry, Notts, who secured the 2d and 3d awards respectively. Out of four capital samples of Madresfield Court, the best came from Mr. W. Earp, gr. to J. S. Sellon, Esq., Hume Towers, Bournemouth; and in the Foster's Seedling class the 1st prize went to Mr. J. Stephenson, gr. to F. Peek, Esq., Roby House, Sydenham, and the 2d to Mr. Miles, Wycombe Abbey. In a very good class of Lady Downe's the best came from Mr. C. Tyler, gr. to R. Gosling, Esq., Hassobury, Bishop's Stortford; Mr. Coleman and Mr. Neighbour, in the order named. There were ten competitors. With Buckland Sweetwater, Mr. C. J. Bungay, gr. to W. Smith, Esq., Herne Hill, was 1st; and in a class for any other kind not previously specified in the schedule, Messrs. H. Lane & Son had a capital dish of Alicante; Mr. Perks, gr. to C. W. Dusseldoff, Esq., Dorchester House, Sydenham, a fine sample of Barbarossa, bloom very rich; and Mr. J. Peed, a dish of Alicante, rather small in berry, but finely coloured, and carrying a fine bloom. Sixteen competed in this class, which included also Mrs. Pince's Black Muscat, Trebbiano, and Chaptal. The heaviest bunch was a good and compact one of Syrian, weighing 10 lb. 10 oz., and shown by Mr. Dickson, gr. to J. Jardine, Esq., Arkleton, Langholm. Mr. J. Peed was 2d with Barbarossa, 5 lb. 8 oz., and Mr. C. Tyler, 3d, with the same variety, weighing 5 lb. 4 oz. Mr. J. R. Pearson's special prizes for the new Grape Golden Queen were not awarded, on the ground that the samples were "not in sufficiently good condition," but as no stipulations of any kind as to condition has so far as we know been published, we think the judges erred in withholding the prizes. No doubt they have a more satisfactory reason, but it ought to be stated.

The best of a dozen Queen Pines, a remarkably handsome fruit, weighing 6 lb. 4 oz., came from Mr. A. Webb, gr. to J. H. Manners Sutton, Esq.; Mr. R. Day, Hillside, Newark-on-Trent, was 2d, with one weighing 5 lb. 2 oz., a good fruit, but having rather too large a crown; and Mr. G. T. Miles, was 3d, the weight of his specimen being 4 lb. 12 oz. Seven fruits were staged in the "any other variety" class, and Mr. C. Ross, gr. to C. Eyre, Esq., Welford Park, Newbury, came in 1st, with a Smooth Cayenne, weighing between 5 lb. and 6 lb., and the individual pips of which were uncommonly well swelled out; Mr. Pragnell, gr. to G. D. W. Digby, Esq., Sherborne Castle, Dorset, was 2d; and Mr. Sandford, gr.

to Earl Bective, Kirkby Lonsdale, 3d, with fine specimens of the same variety.

Peaches and Nectarines were exhibited in good numbers; and, as a whole, were of excellent quality. Out of eighteen dishes of the first-named, a very beautiful one of Lord Palmerston, shown by Mr. Gibson, gr. to F. B. Aikins, Esq., Halstead Place, Sevenoaks, was selected for the highest award; an exceedingly good sample of Barrington, from Mr. Thomas Frost, Bower and Ling Nurseries, Maidstone, coming in 2d; and Princess of Wales, a fine, pale-coloured variety, contributed by Mr. Fry, gr. to L. G. Baker, Esq., Haydon Hall, Eastcott, Finner, was placed 3d. The last-named variety was also well shown by others, as also Reine des Belges, and Noblesse. In the Nectarine class Mr. A. Jamieson, gr. to the Earl of Crawford, Haigh Hall, Wigan, had the best of fifteen samples; a beautiful dish of Prince of Wales, Hunt's Tawny, very good, from Mr. Bolton, gr. to W. Tipping, Esq., Brasted Park, Sevenoaks, coming next. Of red-fleshed Melons there were twenty fruits for the judges to taste, and as a result of their examination a nice fruit of Scarlet Gem, shown by Mr. O. Goldsmith, Polesden Lacey, Dorking, was adjudged 1st; Read's Scarlet, from Mr. Coleman, 2d; and the old Hero of Bath, from Mr. Kneller, Malshanger Park, Basingstoke, 3d. Green-fleshed varieties were represented by twenty-nine fruits, and the best of these were a finely-netted variety, unnamed, from Mr. R. Adams; Eastnor Castle, from Mr. Coleman; and Victory of Bath, from Mr. John Day. The Fig class was the best we have ever seen in an autumn show, and two extra 3d prizes were awarded by the judges. The finest of twenty-three samples was a grand dish of White Marseilles, from Mr. Burnett, gr. to Mrs. Hope, The Deepdene; and splendid specimens of Bruuswick from Mr. Diver, gr. to W. Moore, Esq., Wierton, near Maidstone, and Mr. W. Chisholm, of Boughton Place, near the same Kentish town. Brown Turkey and Brown Genoa were also well shown, but the prevailing sort was the old but excellent Bruuswick. The Cherry class was also an exceedingly good one of Morellos, and the highest award went to Mr. Thomas Jones, Elvetham Park, Winchfield. Of Green Gages, the display was poor in the extreme, only two dishes competing. For a single dish of any variety except the last-named there were some fifteen competitors, and the winners were Mr. Staples, gr. to H. Oppenheim, Esq., Chipstead Place, Sevenoaks, with Coe's Golden Drop; Mr. Walker, Thame, Oxon, with Pond's Seedling; and Mr. James Bolton, with the same variety. Out of eight groups of three dishes each Mr. James Bolton, with Golden Drop, Pond's Seedling, and Magnum Bonum, was placed 1st; the other awards going to Mr. Staples and Mr. James Fry, who staged excellent samples.

The classes for dessert and culinary Apples were unusually good, both in quality and extent, most of the many samples staged being of fine size and very clean growth. In the dessert class the highest award went to Mr. Haycock, Barham Court, Maidstone, who had the Melon Apple, Cox's Orange Pippin, and Ribston Pippin, the latter especially being exceedingly fine. The second award went to Mr. Rutland, gr. to the Duke of Richmond and Gordon, Goodwood, who had grand fruits of King of the Pippins, Webb's Seedling, a flattish, angular-shaped, and highly coloured variety; and Ribston Pippin. Mr. C. Ross came in 3d, with Cox's Orange Pippin, Cornish Aromatic, and Blenheim Orange; and an extra prize went to Mr. Bolton. In the succeeding class, an uncommonly good one, for culinary kinds, Mr. Bowles, gr. to W. Skinner, Esq., Beresford House, Boughton, Maidstone, came in 1st with very large and clean examples of Lord Suffield, Stone Pippin, and Warner's King, an extraordinary fine lot; 2d, Mr. Rutland, with the last-named, Blenheim Orange, and Lord Suffield; and 3d, Mr. T. Bailey, gr. Shardtloes, Amersham, with Grenadier, a very large, green, angular-shaped Apple; Hableton Dux Ans, and Blenheim Orange. The class was so good that three extra 3d prizes were awarded. The dessert Pears were also well shown, but not in such quantities as Apples. Mr. G. Goldsmith, gr. to P. C. Hurdwick, Esq., Hollanden, Tonbridge, sent the finest three dishes—admirable examples of Duchesse d'Angouleme, Beurré d'Amalies, and Williams' Bon Chretien. Mr. Staples, who came in 2d, had the last-named, Marie Louise, and Beurré d'Aremberg. Mr. C. Haycock was a good 3d, and two extra prizes were also awarded. Souvenir du Congrès, Durandau, and Beurré Hardy were beautifully shown by Mr. Haycock.

Unusually extensive and fine was the display of DAHLIAS, and again were the Salisbury flowers unapproachable for size, brightness, and freshness. Mr. Keynes' 1st prize collection of forty-eight show varieties included the cream of the list, and we therefore give their names:—Henry Glasscock, Matilda, Henry Walton, Perfection of Primroses, Masterpiece, Dauntless, John Macpherson, James Cocker, Queen of York, Dictator, Vice-President, A.

Cramond, Herbert Turner, Thos. Goodwin, Ethel Newcombe, Criticism, Rev. J. B. M. Camm, Edward Purchase, J. N. Keynes, Queen of Beauties, Mrs. B.oston, Charles Leicester, John Bennett, Ovid, Hon. S. Herbert, John Standish, Picotee, Queen's Messenger, Mr. Harris, Eccentric, Flag of Truce, Cremorne, Royal Queen, James Service, Henry Bond, J. W. Lord, Princess of Prussia, Luisa Neate, Burgundy, Prince Arthur, Willie Eckford, Flora Wyatt, Mr. John Downie, and a few seedlings. Messrs. Rawlings Brothers were a good 2d, and Mr. Turner 3d. In the fancy class Mr. Keynes had grand blooms of J. B. M. Camm, Maid of Athens, Miss Lily Large, Tippy Bob, Herbert Purchase, Mrs. Saunders, Parrot, Letty Coles, R. Dean, Mons. Chauvere, Carnation, Flora Wyatt, Hercules, Ootoroon, Fanny Sturt, Laura Haslam, Eccentric, Lucy Fawcett, Robert Burns, Henry Glasscock, Enchantress, Miss Bond, Sam Bartlett, and several seedlings. Mr. Searle, of Sevenoaks, Mr. Turner, and Mr. Painter, Smallwood, near Lawton, Cheshire, also exhibited in excellent form. The amateur classes were well filled, but call for no special comment, being a long way behind the nurserymen, except in the case of Mr. Glasscock, of Bishop's Stortford, who took the two 1st prizes.

The following new Dahlias were awarded First-class Certificates:—Rose Circle, a full, well-built, rich deep rosy claret coloured variety, shown by the executors of the late John Harrison, of Catterick Bridge; Charles Lidgard, buff-yellow, tipped with crimson, and very showy, from Mr. Turner; Robert Burns, a fine fancy flower, dark magenta, striped and blotched with dark maroon; Dictator, a very dark scarlet; Emulator, crimson-magenta, as near as we could make it; and Marion, a delicate shade of rosy pink, from Mr. Keynes; and James Willing, dark crimson-magenta, tipped with rosy pink, from Messrs. Rawlings Brothers, Romford.

The GLADIOLUS classes were not particularly noteworthy, and we need only say that Mr. G. Wheeler, Warminster, sent the best thirty-six, and the Rev. H. H. Dombain the best twenty-four. The Messrs. Kelway, of Langport, sent a magnificent stand of seedlings, and received First-class Certificates for Marciannus, orange-scarlet, flaked with crimson, a fine bold flower; Richard Dean, salmon-pink, feathered with crimson; John Laing, rose-lake, feathered deep crimson; and Venulus, a very rich scarlet, with a white throat, and white bar down the segments. The stand also included Duchess of Edinburgh, an immense rose-coloured flower with a white centre—the largest of all, a fine, broad, and excellent shaped flower.

The ASTERS were particularly good in quality and shown in considerable numbers. Mr. Betheridge, of Chipping Norton, sent the best two dozen quilled blooms; and Messrs. Saltmarsh, of Chelmsford, the best twenty-four tasselled. The first-named also had a First-class Certificate for a pretty seedling quilled variety, named Novity.

The VEGETABLE DEPARTMENT was unusually complete and interesting, every vegetable in season being well and abundantly represented. In the open and cottagers' classes there were no less than ten competitors in each, and a very strong competition for the highest awards resulted in each case. In the open class Mr. Pragnell once more took the lead with an extraordinarily creditable lot, which consisted of Maltese Parsnips, Spanish Caroons, Canada Wonder Beans, Salsify, James' Long Keeping Onion, Brussels Sprouts, Green Curled Savoy, Cretan Leeks, Early Horn Carrots, Vegetable Marrows, Veitch's New Autumn Protecting Broccoli, Scorzonera, Breadfruit Potatoes, Ne Plus Ultra Peas, White Spanish Onions, Early Dwarf Ulm Savoys, Autumn Giant Cauliflowers, Veitch's Improved Beet, Red Globe Turnips, Hathaway's Excelsior Tomato, Red Cabbage, Early Snowball Turnips, Naneham Park Onions, William the First Peas, Porter's Excelsior Potatoes, Wheeler's Improved Cabbage, Henry's Prize Leeks, Student Parsnips, Incomparable White Celery, Eastwood's Beet, Early Nantes Carrots, and Scarlet Runner Beans. Mr. C. Chaff, gr. to G. H. Goschen, Esq., Ballards, Addington, was a very good 2d; and Mr. John Durrant, St. George's Terrace, Hurstpierpoint, 3d. In the cottagers' class for not less than six distinct kinds the last-named gentleman came in 1st, with clean and well grown examples of Cauliflowers, Turnips, Carrots, Onions, Potatoes and Peas. The other awards were taken by Mr. Patchell and Mr. Brooks of Bandon Hill, Beddington. The Schoolmaster Potato, shown by Mr. Turner, was awarded a First-class Certificate.

MISCELLANEOUS SUBJECTS were, as usual, a good feature of the show, and extra prizes were awarded to Mr. John Walker, nurseryman, Thame, Oxon, for a choice collection of Asters, and also for a fine sample of selected White Spanish Onions; to Messrs. Paul & Son, The Old Nurseries, Cheshunt, for collection of Apples, sixty sorts; to Mr. J. Peed, Roupell Park Nurseries, Norwood Road, for Grape Vines in pots; to Mr. L. A. Killick, Mount Pleasant, Langley, Maidstone, for a collection of Apples and Pears;

to Mr. C. Ross, gr. to C. Eyre, Esq., Welford Park, Newbury, for a collection of Apples and Pears; to Mr. W. Mowbray, gr. to Earl of Leven, Falmer, Slough, for Grapes, Golden Champion; to Messrs. William Paul & Son, Waltham Cross, for six boxes of cut Roses and for a collection of Apples; to Mr. Rutland, Goodwood, for a fine dish of Grosse Calabasse Pear; to Mr. Wildsmith, for collection of Apples; to Messrs. Kelway & Sons, Langport, for collection of Gladioli; to Mr. T. Jones, The Royal Gardens, Frogmore, for collections of Apples and Pears; to Mr. W. Corp, 84, High Street, Oxford, for ten boxes of cut Roses, splendid for the season; to Messrs. John Laing & Co., Stanstead Park, Forest Hill, for collection of plants; to Messrs. Cranston & Co., King's Acre Nurseries, Hereford, for ten boxes of cut Roses; and to Mr. C. Haycock, Barham Court, Maidstone, for collection of Peaches, Nectarines, and Oranges.

The exhibition also included a choice collection of Tomatos from the Royal Horticultural Society's gardens, Chiswick; a large Gourd, weighing 84 lb., from Messrs. John Laing & Co.; and a very fine fruit of Passiflora quadrangularis, from Mr. Jamieson, Haigh Hall, Wigan. Bouquet Dahlias and Carnations were also liberally shown by Mr. Turner.

Huntingdonshire Horticultural: Sept. 12.—The usual summer show of this Society was held on the above date in the grounds attached to Castle Hill House, Huntingdon. There was a marked improvement this year in both the size and quality of the plants exhibited in the principal classes for flowering and fine-leaved plants, as well as some other departments. In cut flowers the effects of the present exceptional season here, as in most places, was noticeable: Roses, as almost general, were much finer than usual, while Gladioli, generally one of the principal features of autumn exhibitions, were poor, and few in numbers. Dahlias were well shown, as also Asters. Hollyhocks, it would almost seem, are doomed to succumb to the disease of late years so prevalent, for they were the merest shadows of what they once were.

The competition for the silver cup offered by the Society for twelve stove or greenhouse plants was very close, but was awarded to Mr. Lewis, gr. to D. Herbert, Esq., Huntingdon. His collection included *Fransceca calycina*, *Dipladenia amabilis*, *Rondeletia speciosa*, *Clerodendron Balfourianum* and *Croton undulatus* and *variegatus*, both well coloured. Mr. Smith, gr. to Miss Cheere, Papworth Hall, 2d; his best were *Eucharis amazonica*, *Dipladenia amabilis*, with unusually large flowers; a nicely grown variegated Pine, and *Maranta lineata-rosea*. In another class of twelve stove and greenhouse plants Mr. Lewis also took 1st, showing amongst others a pretty example of the pink-flowered *Chironia*.

In Ferns the exhibitors confined themselves to comparatively small growing kinds, which if they do not possess the commanding appearance of the large tree species are more elegant. For six, Mr. Tilbrook, gr. to A. Brown, Esq., took the lead; Mr. Bowie, gr. to the Earl of Sandwich, 2d. The best six *Fuchsias* came from Mr. Wixon, gr. to Mrs. Lawrence, Hemingford. In Zonal Pelargoniums Mr. Tilbrook was 1st, with plants well flowered and not too stiffly trained.

There were a number of competitors in the class for dinner-table plants, the majority here, as often elsewhere, staging close-habited subjects quite unfit for the purpose, and in many cases much too large, which made them still more unsuitable. Messrs. Wood & Ingram, Huntingdon, were 1st. For the Rev. H. Bree's special prize for the best arrangement of cut flowers for table decoration (confined to lady competitors), the judges had to decide betwixt examples made up of glaring, high-coloured flowers, too closely packed together, with insufficient green material to relieve them, and one—exhibited by Miss Ansley—who erred in the opposite direction by a simple and somewhat too meagre display; but as this is much less objectionable than overdose combinations, it was awarded the 1st prize.

The Mayor's silver cup for twenty-four Asters was well won by Mr. Petfield, gr. to A. J. Thornhill, Esq., Diddington. Messrs. Wood & Ingram showed the best twenty-four Dahlias, Twelve Roses.—Mr. Cooper, the Rev. E. Fellowes, and Messrs. Wood & Ingram took the prizes in the order named.

Fruit.—The best eight dishes were shown by Mr. Tilbrook, who had nice Black Hamburg and Muscat of Alexandria Grapes, Peaches and Nectarines, Figs and Plums. For black Grapes Mr. Cooper was 1st, with nicely finished Black Hamburgs, two bunches growing on one shoot. In white Grapes Mr. Bowie was successful, showing even bunches of Muscat of Alexandria. Six Peaches.—1st, Mr. Strachan, gr. to the Rev. Canon Linton. Six Nectarines.—1st, Mr. Tilbrook. (From a Correspondent.)

Bradford Abbas, Dorset.—The cottage garden show held in this village on Wednesday last was one of the most successful of any previous year. It was

established by Professor Buckman, to encourage the growth among cottagers of some other vegetables besides Potatoes, as well as to encourage the cultivation of window and garden flowers; and it was pleasing to see that while all the best sorts of Potatoes were this year well grown, Peas, Kidney Beans, Carrots, Parsnips, &c., were not neglected. The Onions were particularly fine, and with so many sorts it was difficult to award the prize.

The show of flowers at this time of year was somewhat limited, but there were some elegant and tasteful designs in the different bouquets of garden productions, whilst the devices in wild flowers, mostly done by the children of the district school, were so truly exquisite as to have got special commendations from Prof. Buckman, who, in his remarks upon the show, descanted upon the health-giving properties of a variety of vegetables, and the no less good effects to the moral health of a love of flowers, pointing out that the poor man, equally with the rich, might have good vegetables served on a table ornamented with flowers, than which few are more charming than are wild ones, especially when arranged with taste; and the educating this taste with regard to flowers was good in every way.

Thanks were accorded to the Messrs. Sutton, who had kindly contributed collections of seeds for the cottagers, and as these were always of the best, and of good soils, it sufficiently accounted for the excellent vegetables shown.

- Sept. 20.—A dull, miserable, cold day. Overcast throughout. Rain fell till 5 P.M.
- 21.—A fine clear day. Cloudy, with a shower of rain at 2 P.M. Cold.
- 22.—A very fine bright day. Cold.
- 23.—Generally dull and cloudy. Little rain fell in the morning.
- 24.—A very fine day. Cloudy at times. Cold. Cloudless at night.
- 25.—A fine day, but cloudy and gloomy. Cold.
- 26.—A fine bright day. Cool. Cloudless at night.

LONDON: *Barometer*.—During the week ending Saturday, September 22, in the vicinity of London the reading of the barometer at the level of the sea increased from 30.18 inches at the beginning of the week to 30.33 inches by the morning of the 16th, decreased to 30.27 inches by the evening of the same day, increased to 30.34 inches by the evening of the 17th, decreased to 29.78 inches by the evening of the 20th, and increased to 29.97 inches by the end of the week. The mean reading for the week at sea level was 30.07 inches, being 0.12 inch above that of the preceding week, and 0.05 inch above the average.

Temperature.—The highest temperatures of the air observed by day varied from 63.3° on the 16th to 53.3° on the 20th; the mean value for the week was 59.4°. The lowest temperatures of the air ranged from 39.1° on the 21st to 52.3° on the 19th; the mean for the week was 46.3°. The mean daily range of temperature in the week was 12.3°, the greatest range in the day being 18.1°, on the 22d, and the least 6.8°, on the 20th.

The mean daily temperatures of the air were as follows:—16th, 53°.8; 17th, 53°.6; 18th, 53°.8; 19th, 55°.3; 20th, 49°.8; 21st, 47°.7; 22d, 48°.5; and the departures in defect of their respective

averages were 3°.1, 3°, 2°.8, 0°.8, 6°, 8°.5, 6°.8. The mean temperature of the air for the week was 51°.7, being 4°.4 below the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 114° on the 18th, and 118° on the 22d; on the 20th the reading did not rise above 60°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 31° on the 22d, 31° on the 21st, and 35° on the 16th. The mean value for the week was 37°.

Wind.—The direction of the wind was N., and its strength gentle. The weather during the week was generally dull and cold, and the sky partially cloudy. Fog prevailed on the 16th.

Rain fell on two days during the week; the amount measured was 0.16 inch.

ENGLAND: *Temperature.*—The highest temperatures of the air observed by day were 68° at Bristol, 67° at Truro, and 66° at Nottingham and Eccles; the highest temperature of the air at Liverpool was 59°; the mean value from all stations was 64°. The lowest temperatures of the air observed by night were 33° at Truro, 36° at Wolverhampton, and 37° at Bristol; at Sunderland the lowest temperature was 43°; the general mean from all stations was 39°. The range of temperature in the week was the greatest at Truro, 34°, and the least at Liverpool, 17°; the mean range from all stations was 24°.

The mean of the seven high day temperatures was the highest at Truro, 63°, and Plymouth, 63°, and the lowest at Wolverhampton and Liverpool, both 57°; the mean from all stations was 59°. The mean of the seven low night temperatures was the lowest at Truro, 42°, and Wolverhampton, 43°, and the highest at Norwich and Sunderland, both 47°; the mean value from all stations was 45°. The mean daily range of temperature in the week was the least at Liverpool, 9°, and the greatest at Truro, 21°; the mean daily range of temperature from all stations was 13°.

The mean temperature of the air for the week from all stations was 51°, being 5° lower than the value for the corresponding week in 1876. The highest was 54°, at Plymouth, and the lowest 49°, at Wolverhampton and Eccles.

Rain.—The amounts of rain measured during the week were small, and varied from four-tenths of an inch at Norwich and Sunderland to one-hundredth of an inch at Bristol: at Truro no rain fell, the average fall over the country was two-tenths of an inch nearly.

The weather during the week was generally dull and cold, and the sky cloudy.

SCOTLAND: *Temperature.*—The highest temperatures of the air varied from 69° at Dundee to 61° at Aberdeen; the average value from all stations was 65°. The lowest temperatures of the air ranged from 35° at Paisley to 41° at Aberdeen; the mean value from all stations was 39°. The mean range of temperature in the week from all stations was 26°.

The mean temperature of the air for the week from all stations was 51°, being 2° lower than the value for the corresponding week in 1876. The highest was 53°, at Greenock, and the lowest 49°, at Paisley.

Rain.—The amounts of rain measured at Edinburgh, Aberdeen, and Leith were 0.05 inch, 0.41 inch, and 0.07 inch respectively. At Glasgow, Dundee, Greenock, and Paisley no rain was measured. The average fall over the country was one-tenth of an inch.

DUBLIN.—The highest temperature of the air was 61°, the lowest 38°, the range 22°, the mean 51°, and the fall of rain 0.02 inch.

JAMES GLAISHER.

Variorum.

AN OLD FIR PLANK.—Through the kind interest which Sir Robert Christison, Bart., takes in all things arboricultural, the public have now an opportunity of seeing in the National Industrial Museum of Science and Art at Edinburgh a curious relic of the ancient Forest of Glenmore, and of judging of the quality and valuable properties of the native Scots Fir timber. At the request of Sir Robert, the Duke of Richmond and Gordon has sent for exhibition in the Museum a plank of Scots Fir, 5 feet 7 inches wide at the bottom, which was presented in 1806 to the then Duke, by the person who purchased and cut down the whole of Glenmore Forest. It bears its rather curious history on a brass plate affixed to its face, of which the following is a verbatim and literal copy:—

"In the year 1783, William Osbourne, Esq., merchant of Hull, purchased of the Duke of Gordon the Forest of Glenmore, the whole of which he cut down in the space of twenty-two years, and built during that time at the mouth of the River Spey, where never vessel was

built before, forty-seven sail of ships of upwards of 19,000 tons burthen. The largest of them, of 1050 tons, and three others but little inferior in size, are now in the service of His Majesty, and the Honourable East India Company. This undertaking was completed at the expense (for labour only) of above £70,000.

"To His Grace the Duke of Gordon this plank is offered as a specimen of the growth of one of the trees in the above forest by His Grace's most obedient servant,

"Hull, Sept. 26, 1805."

"W. OSBOURNE.

Sir Robert Christison has, with his usual accurate criticism, examined this plank, and reports to us as follows regarding the tree from which it had been taken:—

"The tree must have been 19 feet in girth at the bottom of the plank, and 16 at top, 6 feet 3 inches higher up. I can make out 243 layers on one radius; seven are wanting in the centre, and seven years at least must be added for the growth of the tree to the place of measurement. Hence the tree must have been about 260 years old. The out layers on this radius are so wide that it must have been growing at a goodly rate when it was cut down."

The plank is in the front corridor, immediately on the left hand as one enters the main hall of the museum, leaning against the wall which partitions off the corridor from the body of the hall. We call attention to this highly interesting historical arboricultural relic in order that many of our Northern subscribers, when in Edinburgh, may visit the Industrial Museum there, and inspect it for themselves, feeling sure that after seeing so noble a specimen plant of indigenous Scots Fir timber, they will share with us in the regret that not one specimen tree of this forest was spared by its ruthless destroyer, either to transmit to future ages the seeds of so noble and lofty a line, or to mark the spot where once stood so many monarchs of the forest. *The Journal of Forestry.*

Enquiries.

He that questioneth much shall learn much.—BACON.

208. THE COST OF BURNING CLAY LANO.—Can any of your readers inform me what the cost of burning heavy clay land would be per acre? I have some thoughts of taking a few acres near Derby for workmen's allotments, but the land is heavy; is there any better way of rendering it fit for gardens than burning? The surface has been cultivated as arable land, so that the second or third spit would be the part to burn, I should think. Slack is cheap, as are hedge clippings. Any practical hints as to the best mode of attaining my object, viz., converting stiff clay into garden ground, will much oblige. Town refuse and ashes could be had almost for the carting. *R. Binns, Derby.*

209. THE GRAND COS LETTUCE.—Mr. Judd, The Castle Gardens, Warwick, is desirous of obtaining, true, a little seed of a Lettuce sent out under this name last year by Messrs. Gibbs. Mr. Judd describes the plant as a sort of hybrid between a Cabbage and a Cos Lettuce, and he will gladly pay any reasonable price for a little to sow at once.

Answers to Correspondents.

CHERRIES FOR NORTH WALL: *J. A.* Plant May Duke. You might also try Frogmore Early, Knight's Early Black, and Early Rivers.

CLERODENDRON BALFOURIANUM: *G. W.* We will endeavour to meet your wishes shortly.

CONIFER: *A. W. Child.* It is not at all unusual for Conifers to produce sprays with two forms of foliage, as in the specimen you send us. If you look closely you will find that the Cupressine, to which group your specimen belongs, produce needle-shaped leaves in the young seedling state, and that later on, as growth progresses, the more mature scale-like leaves are formed, which give the branches quite a different appearance. Your plant has merely borne a shoot on which both these forms are developed, and this, as we have already said, is not at all an uncommon occurrence.

HEATING SMALL GREENHOUSES: *T. H.* We should much prefer a gas stove outside, with hot-water pipes inside, as the safest and most effectual plan. The gas burner can be fixed so as to heat a small boiler in an ordinary furnace provided with a door, and is then very little trouble to manage, while the plants are perfectly safe. Petroleum stoves may be safely used with care, but we prefer the other plan.

MONSTROUS PEAR: *R. Lowe.* We have seen many somewhat similar cases, and have published illustrations of some of them.

NAMES OF PLANTS: *W. E.* 1, *Physostegia imbricata*; 2, *Muhlenbeckia adpressa*; 3, *Cratogeomys Azarolus*?—*A. B.* *Saponaria officinalis*.—*J. S.* 1, *Saccharum sp.*; 2, *Imperata cylindrica*?; 3, *Phloxum pratense*?; 5, *Plantago maritima*; 6, *Aira cespitosa*; 7, *Koeleria cristata*?—*D. D.* *Monarda didyma*.—*W. G. K.*

Dendrobium aequum.—*J. Murton.* *Odontoglossum Lindleyanum*.—*G. L.* 1, *Sedum abscensum*; 2, *Sedum spurium* var.; 3, *S. album* var.; 4, *Saxifraga cuneifolia*; 5 and 6, too incomplete to name.—*A. G. T.* *Aster novae-angliae*?; 2, *A. levis*?; 3, *A. simplex*?. The scraps were too bad to name with any degree of certainty. 4, *Linaria striata*; 5, *Aconitum Napellus*.—*T. W. W.* Only two were numbered when they reached us. 1, *Juniperus thurifera*; and 3, *J. excelsa*. The others are *Juniperus communis*, *Cupressus sempervirens*, and *C. nutkaensis*, which may probably be the same as the one alluded to as No. 5.—*W. R.* The common Ling, *Calluna vulgaris*.—*H. D.* *Pinus Laricio calabrica*.—*J. E.* *Colchicum variegatum*.

PENTSTEMONS: *Downie & Laird.* They are a very fine lot, but a little the worse for travelling when they reached us. Mrs. Fox Perret, a rich mulberry-purple with white centre; Charles Mitchell, a rich maroon crimson; Andrew Hunter, brighter crimson with white centre; William Kelway, one of the purples; Archibald Fowler and John F. Kinghorn, maroon crimsons, seem to be exceptionally good.

ROSE SPORT: *H. C.* The Rose which has sported, producing two colours in the flower, is new to us, and certainly worth propagating with a view to prove its constancy.

THE VINERIES AT ARDS.—Mr. Cross writes that he has no desire to impute blame or give pain to any one. The only object in writing was to show an easily applied remedy for exhausted Vines in outside borders.

VIOLA: *W. Paul.* The Viola has large, well-formed, clear sulphur-yellow flowers, with merely a few short lines radiating from the eye, so that it is practically self-coloured. If, as you say, the habit is dwarf and free blooming, it will be a useful variety of the pale yellow series. There is nothing to be desired in the individual flowers as sent to us.

ERRATUM.—At p. 368, for "Tritonia aurea" read "Urcolina aurea."

CATALOGUES RECEIVED:—*W. Rumsey* (Waltham Cross, N.), Select List of Roses, Trees and Shrubs, Fruit Trees, Bulbs, &c.—*Messrs. E. G. SEEDS.

LONDON: September 26.—Nothing of special importance or interest has this week transpired in connection with the trade for farm seeds. As respects the leading descriptions of Clover, seed merchants appear resolved to adopt this season a policy of extreme caution, and they resolutely refuse to operate unless at the moderate quotations which in their judgment the promised abundance of supply will alone justify. For Winter Tares the demand continues very active; no excessive quantity has come forward, and, consequently, the late advance is fully maintained. For sowing Rye occasional orders drop in, which are executed on former terms. The stock of Trifolium incarnatum seems about used up, the market being almost completely cleared of fine parcels. Hemp and Canary seed are without quotable change. The same can be said of both Rape and Mustard seed. Feeding Linseed is in good request, and the tendency of values is upward. The blue Pea crop has proved this year disappointing, both as to yield and quality; holders of handsome samples have, therefore, advanced their demands 1s. to 2s. per qr. There has been more business doing in grass seeds. A noteworthy feature of the present week has been an eager speculative inquiry for Trefoil and Alsike seeds. Some accounts just received speak unfavourably of the new French Lucerne, and state that prices in France are creeping up. Information is awaited with interest as to the Clover crop of the United States, and also of Canada. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.*

CORN.

At Mark Lane on Monday good and fine qualities of Wheat realised full prices to 1s. per quarter advance; but inferior produce met with a slow and irregular sale at about previous rates. Foreign wheat was in moderate supply, and the tendency was in an upward direction. Barley of fine quality suited for superior malt realised high quotations. Medium qualities and feeding descriptions were well supported. Malt was firm, with an upward tendency; choice qualities were held at high quotations. Oats were firm at fully late rates. For Indian Corn the trade was firm, with an upward tendency. Beans and Peas sold at late rates. For flour an advance of 6d. per sack and barrel on the prices of Monday se'night was quoted.—On Thursday the trade for the better qualities of Wheat was not active, but former prices were about supported. Inferior produce was dull, and irregular in value. Foreign Wheat of good and fine quality was held at full rates. Choice Barley was scarce and dear; for medium kinds there was a steady demand at previous currencies. Oats were in moderate request, at late rates, but Indian Corn sold slowly at about previous quotations. Beans and Peas were unaltered in value. For flour the trade was quiet on former terms.—Average prices of corn for the week ending Sept. 22:—Wheat, 57s. 6d.; Barley, 43s. 8d.; Oats, 25s. 10d. For the corresponding period last year:—Wheat, 47s.; Barley, 38s. 6d.; Oats, 26s.

CATTLE.

At the Metropolitan Market on Monday, the supply of beasts being small prices advanced, and a fair clearance was effected. There were not quite so many sheep, and trade was more active, and choicest kinds rather dearer. Choice calves were also dearer. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 8d. to 6s. 2d.; calves, 5s. to 6s. 4d.; sheep, 5s. 6d. to 6s., and 6s. 6d. to 7s. 2d.; pigs, 4s. to 5s. 4d.—On Thursday trade was decidedly dull. Supplies both of beasts and sheep were rather above the average for a Thursday, and as the demand was not active, prices gave way. Calves also were dull and lower.

HAY.

The Whitechapel report for Tuesday states that a large supply of fodder was on sale at that day's market, but trade rather dull. Clover gave way in price. Quotations:—Prime old Clover, 100s. to 145s.; inferior, 85s. to 95s.; good new, 100s. to 135s.; prime old meadow hay, 90s. to 120s.; inferior, 70s. to 85s.; good new, 80s. to 120s.; and straw, 44s. to 57s. per load.—At Thursday's market there was a large supply on sale, but with a dull trade prices were with difficulty maintained.—Cumberland Market quotations:—Superior meadow hay, 110s. to 120s.; inferior, 88s. to 100s.; superior Clover, 138s. to 147s.; inferior, 105s. to 112s.; and straw, 55s. to 60s. per load.

POTATOS.

The Borough and Spitalfields markets reports state that moderate supplies are on sale, and the trade steady at former quotations:—Kent Regents, 95s. to 120s. per ton; Essex ditto, 85s. to 110s.; Victorias, 100s. to 130s.; kidneys, 80s. to 120s.; Early Rose, 90s. to 115s.; rocks, 80s. to 90s.—The imports into London last week comprised 3910 bags from Hamburg, 568 bags 112 sacks Boulogne, 335 bags Antwerp, 74 baskets Amsterdam, 232 bags Harlingen, 400 Bremen, and 10 baskets Rotterdam.

Sole English Medallists for the Best Hot-Water Apparatus at the United States International Centennial Exhibition, Philadelphia.

Foundation Plate ..	35 0	45 0	60 0	75 0	90 0
Smokestack, Damper, and Soot-Door ..	30 0	30 0	40 0	40 0	40 0
Furnace and Ash-Pit, Frame and Doors; also Furnace Bars, Bearers, Dumb-Plate, &c. ..	30 0	40 0	50 0	60 0	70 0

Foundation Plates are arranged to heat the air before it is sent into the ash-pit at back, and furnace-doors to heat the air before its admission into the furnace, furnishing in fact two "hot air" blasts to the furnace; the admission of large volumes of cold air being most injurious to the economical working of the furnace.

In preparation an entirely NEW SERIES of SEVENTY BOILERS, embracing a large variety suitable for small places, &c., and all specially adapted for low situations where shallow boilers are a necessity. Particulars on application.

WM. WRIGHT & CO., AIRDRIE, N.B.

Under the Patronage of the Queen. J. SMITH'S IMPERISHABLE STRATFORD LABELS.

The above Labels are made of a White Metal, with RAISED BLACK-FACED LETTERS. The *Gardeners' Magazine* says:—"We must give the palm before all other plant labels, as the very first in merit." Samples and Price Lists free.

J. SMITH, The Royal Label Factory, Stratford-on-Avon.

HEREMAN AND MORTON, 2, Gloucester Street, Regent's Park, London, N.W.

LASCELLES' PATENT BENT WOOD CONSERVATORIES AND GREENHOUSES.—All Gardeners know that Wood is better than Iron for Plant Growing, and by the above system a handsome curved house can be erected as cheaply as a plain straight one.
 The curved house is more durable, stronger, lighter in construction, and no best glass is required.
W. H. LASCELLES, 121, Bunhill Row, London, E.C., will supply Drawings and Estimates free of charge.

RICHARDSON'S PATENT HORTICULTURAL BUILDINGS

SECTION OF PATENT ROOF VENTILATOR

Illustrations, Price Lists, and Testimonials free.

Hot-water Apparatus fixed in any part of the Kingdom, and guaranteed.

W. RICHARDSON & CO., Horticultural Builders & Hot-water Engineers, **DARLINGTON**.

CRITCHLEY'S PATENT HEAT REGULATOR,
 AN APPARATUS FOR REGULATING THE HEAT IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe or Supply of Water from Boiler. C, D, Pipes for Circulating Hot-Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.

The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.

The following Testimonial has been received:—

Derkeley Castle, April 13, 1875.

"Gentlemen, — I am happy to inform you, now that the late severe winter is past, that the Hot-Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it the greatest improvement that has come out for horticultural purposes.

"I am, Gentlemen, yours truly, "R. H. CRONK, "Gardener to the Right Hon. Lord Fitzhardinge."

Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

Healthy Heat twenty-four hours or longer for about 1d., without attention. For Bedrooms, Greenhouses, or almost any purpose. Prospectus and authenticated Testimonials sent. In use daily at Patentee's, **THOMAS ROBERTS**,

112, Victoria Street, Westminster, S.W.

JOSEPH BRAMHAM, HORTICULTURAL and HOT-WATER ENGINEER, WIRE WORKER, WEAVER, &c., 104, Dale Street, and 44, Elizabeth Street, Liverpool.
 J. B. strongly recommends the **ALLERTON TRIORY BOILER** as one of the most powerful for extensive work. He has fixed one capable of heating 10,000 feet of 4-inch piping. See *Gardeners' Chronicle*, p. 647. Also his **WELDED WROUGHT IRON WATERWAY BACK** for ordinary Saddle Boilers. These Backs can be fixed to any boiler now in use, and are a great saving in fuel and labour. He is also prepared to fix any kind of boiler made.
 Manufacturer of the Registered **LIVER FRONT** for large Boilers, IRON and WIRE WORK in all branches. References from Noblemen and Gentlemen for work done.
 Plans and Estimates given.

STEVENS' TRENTHAM GREENHOUSE BOILER,
 After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved.

Copy of a Testimonial.

"Royal Exotic Nursery, King's Road, Chelsea, S.W.—Aug. 8, 1877.
 "GENTLEMEN.—In reply to your enquiry as to our opinion of your Stevens' Trencham Boilers, we do not hesitate to pronounce them to be *by far the best* Boilers we have ever used. Our establishment is a very large one, and we have tested most of the various descriptions of Boilers which have been brought out from time to time. We originally commenced with one Trencham Boiler, and we have now *thirteen* of various sizes at work. For certainty of action, economy in fuel, and freedom from breakdown, we have never had a Boiler at all equal to the Stevens' Riveted Trencham Boilers supplied by you, and we have never felt so little anxiety in connection with our hot-houses during the cold winter months as we do now.
 "We are not in the habit of giving testimonials, but we think this may fairly be an exception to our rule, as the matter is one of such importance to the Gardening Public generally, and our experience has led us to form a very decided opinion.
 "We are, Gentlemen, yours faithfully,
 "JAMES VEITCH AND SONS."

For Illustrations, with full particulars, apply to the Sole Makers,
F. & J. SILVESTER,

HOT-WATER ENGINEERS, &c., &c.,
 Castle Hill Works, Newcastle, Staffordshire.
 Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

SADDLE BOILER, 36 inches, with Connections in good order, to be sold for £7. Also some 4-inch PIPE and ELBOWS, and an UPRIGHT TUBULAR BOILER, 33 inches (wants some tubes), at
LETCHFORD'S WORKS, Bethnal Green Junction, E.

FOR SALE, a 48-inch (Meiklejohn's) CRUCIFORM BOILER; only in work two years, as good as new. Taken out because three more houses were added. Price £24, being half the cost price. Apply
PERKINS AND SONS, Park Nursery, Coventry.

For Sale, a
STEVENS' IMPROVED TRENTHAM WROUGHT IRON HORTICULTURAL BOILER, 6 feet long by 3 feet diameter, fitted with Inlet and two Outlet Pipes, Fire-door and Grate complete. For price and particulars apply to
HILL AND SMITH, Brierley Hill Ironworks, Dudley.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.
 "The *Ryleys, Alderly Edge, Manchester.*—Messrs. Hill & Smith.—Sir,—For some 20 years I have used your 'Black Varnish', and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted.
 —Yours respectfully, ALFRED LOWE, J.P."

Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 118, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

HORTICULTURAL WINDOW GLASS.
 —A large variety of sizes, 15-oz., 22s. 6d.; 21-oz., 16s. 6d. per 100 feet. Large sizes, in Cases, for Cutting up—15-oz. 4ths, 36s.; 3ds, 46s. per 100 feet;—21-oz. 4ths, 36s.; 3ds, 46s. per 100 feet.—ALFRED SYBER, Glass, Lead, Zinc, Oil, and Colour Merchant, 8, Pentonville Road, London, N.

BELGIAN GLASS for GREENHOUSES, &c.,
 Can be obtained in all sizes and qualities, of
BETHAM & SON,
 9, LOWER THAMES STREET, LONDON, E.C.
 B. & Son have always a large Stock in London of 20-in. by 12-in., 20-in. by 14-in., 20-in. by 16-in., in 16-oz. and 21-oz.

PARSONS, Gardener to Captain Blake, Danesbury, Welwyn, Herts, can with confidence recommend his Foreman, Henry Mount, to any Lady or Gentleman requiring the services of a man thoroughly practical in all branches of Gardening; has been with him seven years.—Address as above.

GARDENER (HEAD), where not less than four are kept.—Age 37, married; thoroughly experienced; competent to undertake any improvement connected with a Gentleman's Establishment where energy and intelligence are required. Highly recommended.—A. G., Barham, East Hoathly, Sussex.

GARDENER (HEAD), to any Lady or Gentleman requiring the services of a thorough practical man in every branch of Gardening.—Age 38, married; twenty-two years' experience in England and Scotland. Three years' and a half good character from last situation.—A. McC., Messrs. William Paul & Son, Nurseries, Waltham Cross, Herts.

GARDENER (HEAD), where three or more are kept.—Age 28, single; thoroughly understands Gardening in all its branches; has been in some of the best Places in Ireland and Scotland. Can be highly recommended for abilities and general character.—W. J. W., Penninghame Gardens, Newton Stewart, Wigtownshire.

GARDENER (HEAD), where three or more are kept.—Age 30, married; Scotch; fourteen years' experience; understands Gardening in all its branches, and could take the Management of a small Estate. Open for engagement about the beginning of November next. First-class references.—T. McK., The Gardens, Aytton, Bridge of Earn, Perthshire, N. B.

GARDENER (HEAD), and BAILIFF.—JOHN KITTELY, Head Gardener and Bailiff to Sir J. P. Grant for the past twelve years, is open to a re-employment. Highly recommended.—Prospect House, Bath.

GARDENER (HEAD, WORKING).—Age 29, single; thorough practical knowledge of the profession in all its branches; fifteen years' experience. Good character from last and previous situations.—J. R. W., 1, Prospect Place, Holly Walk, Hampstead, N. W.

GARDENER (good SECOND), where several are employed.—Within 25 miles of London preferred.—For full particulars apply to X. V. Z., Post-office, Moreton-in-Marsh, Gloucestershire.

GARDENER (good SECOND).—Age 21; seven years' experience. Good knowledge of Stove and Greenhouse Plants, Early and Late Forcing, and the general routine of Gardening. Good references.—A. M., 5, Clewer Village, Windsor, Berks.

GARDENER (SECOND).—Age 21. Good character.—State wages and particulars to H. LININGTON, Fernwood, Wimbledon Park, Surrey.

GARDENER (SECOND), or JOURNEY-MAN, in a Gentleman's Establishment.—Age 21; six years' experience. Good references.—G. HARVEY, The Nursery, Wothorpe, Stamford.

GARDENER (SECOND), where three or more are kept.—Age 22; has a good knowledge of Flower and Kitchen Gardening, and a full knowledge of Stove and Greenhouse Plants. Good character. Please state wages. P. M., 11, Charles Street, Upper Sydenham, Kent, S. E.

GARDENER (UNDER), or SECOND, where two or three are kept.—Age 24, single; respectable. Good references. Please state wages, &c.—A. SONGHURST, Doods Road, Reigate, Surrey.

GARDENER (UNDER).—Age 18, respect-able; five years' experience, and five years' good character.—J. B., Mr. Gibson's, Ascot Heath, Staines.

GARDENER (UNDER), in the Houses, under a Foreman.—Age 20. Two years' good character from present situation.—W. GRANT, Milton Abbey Gardens, Blandford, Dorset.

GARDENER (UNDER).—Age 28, married; seven years' practical experience in all branches. Can be highly recommended. Please state wages.—C. S., The Gardens, Aldershot Park, Aldershot, Hants.

GARDENER (JOURNEYMAN), in a Large Establishment, in the Houses.—Age 21; has a good general knowledge. Good character.—W. H., Lower Bullingham, Herefordshire.

JOURNEYMAN, in a Large Establishment, or **FOREMAN** in a smaller place.—Age 24; good knowledge of the general routine in all its branches. Good references. Please state wages.—H. M., Post-office, Chichester, Sussex.

FOREMAN, or SECOND, in a Gentleman's Garden.—Age 24; has a good general knowledge of the profession. Three years' good character.—K., 1, Clifton Terrace, Nightingale Road, Wood Green, N.

FOREMAN, in a Nobleman's or Gentleman's Establishment.—Age 23; eleven years' good experience. First-class references.—J. C. S., Castle Hill Gardens, Huntingdon.

FOREMAN.—Age 22; eleven years' experience. Has had the Management of present situation twelve months.—H. E. B., The Gardens, Leadenham, Grantham.

To Nurserymen.

FOREMAN (GENERAL), or to take the Management of the Glass Department.—Has had several years' experience in the London and Provincial Nurseries, and now wishes an engagement with an enterprising Nurseryman; near London preferred. Will be disengaged the first week in November. References the best possible.—**SEMPER FIDELIS**, 1, Bridge Street, Fulham, S. W.

PROPAGATOR, FOREMAN, or ASSIST-ANT (INDOOR).—Long experience in Growing Hard and Soft-wooded Plants, Propagating, and Grafting.—**ALPHA**, 6, Barrow Hill Road, St. John's Wood, N. W.

IMPROVER, in a Flower or Kitchen Garden.—Age 18. Good character.—W. CLAVDON, Knote Gardens, Sevenoaks, Kent.

To the Nursery and Seed Trade.

TRAVELLER.—A Gentleman of experience will shortly be open to an engagement as above; has a first-class connection over the North of England. Satisfactory references can be had by applying.—X. Y. Z., Minier & Co., 60, Strand, London, W. C.

SHOPMAN (ASSISTANT), in Wholesale Shop or Warehouse.—Age 20; several years' experience. Good references.—W. W., Victoria and Paradise Nurseries, Upper Holloway, N.

SHOPMAN (ASSISTANT), in Wholesale Warehouse, or **BOOK-KEEPER.**—Age 27; has a good knowledge of the Seed Trade.—J. FALCONER, St. Nicholas, Richmond, Yorkshire.

KINAHAN'S LL WHISKY. Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples are soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for **ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION;** and the safest aperient for delicate Constitutions, Ladies, Children, and Infants. **DINNEFORD AND CO.** 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S OINTMENT and PILLS.

—Autumn is proverbially the season of sickness; then the blood requires purification, the digestion demands thorough and attentive regulation, and all the secretions call for correction. Holloway's remedies supply all these necessities for securing health; the one overcomes Cutaneous Diseases, Sores, Ulcerations, Abscesses and Carbuncles, and all visible imperfections; the other acts most potently in Cleansing the Circulation, Strengthening the Stomach, Governing the Liver, Regulating the Bowels, and reducing the entire system to order. Thus these twin medicaments furnish the most efficient Medicine Chest available for family use. It is easier through Holloway's discovery to point out the remedy than to describe the disease—into the former no fallacy can intrude; into the latter prejudice may unwittingly creep.

Cures (this week) by

DR. LOCOCK'S PULMONIC WAFERS.—Coughs, Colds, Consumption, Asthma, and Bronchial Affections, are quickly and surely removed by them.—From Mr. MORRIS, 157, West Derby Road, Liverpool. Sold by all Druggists at 1s. 3/4d. per box.

THE HUNDRED GUINEA CONSERVATORY

ART-WITH-ECONOMY-APPLIED-TO-CONSERVATORIES

PRIZE
4
MEDALS

FIXED
ANYWHERE

In consequence of the increasing demand for Conservatories, in which pure art is combined with moderate cost, T. H. P. DENNIS & Co. have been led to introduce designs of a character hitherto unknown. One of these designs, showing a house 22 feet 6 inches X 13 feet 6 inches, is annexed, and the result, as regards the extremely low price (which includes fixing, glazing, painting, carriage, &c.), has been attained only by special machinery and a system of interchangeable parts.

T. H. P. DENNIS & Co. are also prepared to provide and fix Hot-water Heating Apparatus and Horticultural Buildings of any dimension or description.

Full-sized specimens of Greenhouses, &c., and Hot-water Apparatus in work, can be inspected at Manshon House Buildings, London, E.C.

Gentlemen waited upon at their residences by experienced designers.

Estimates and Plans free.

PAXTON'S CALENDAR.

Now Ready, a New and thoroughly Revised Edition of the

COTTAGER'S CALENDAR OF GARDEN OPERATIONS.

ORIGINALLY COMPILED BY THE LATE SIR JOSEPH PAXTON, M.P.

OPINIONS OF THE PRESS.

"It has been carefully revised by an experienced gardener, and the lists of vegetables, fruit, and flowers have been corrected by the substitution of the most approved modern kinds, in place of those which were mentioned in the first edition, and many of which have ceased to be worthy of cultivation. It is a thoroughly sound, practical treatise; but it has been so long before the public, and so deservedly appreciated, that any special commendation of it now is unnecessary."—*Midland Counties Herald*.

"This is a handy volume, consisting of seventy pages of letterpress and illustration, containing much and varied information likely to prove useful to all cottagers, &c., who possess a garden. To all such, who require a cheap and reliable book of reference, we heartily recommend it."—*Lloyd's*.

"We are quite glad to see this useful little book once more, and it is like a whiff of perfume from the heather in bloom to read on the wrapper 'two hundred and twenty-first thousand.' We advise all who are interested in the promotion of cottage gardening to sow this little book broadcast."—*Gardeners' Magazine*.

"The information conveyed in this little book is well adapted for all persons having small plots of ground. The necessary operations for each month are clearly laid down, and are of a thoroughly practical nature. The sorts of both fruit and vegetables are well selected, many of them being excellent in quality. To our readers who are interested in the cultivation of their flower and kitchen gardens, we can safely recommend this as being a most concise and useful work."—*Bell's Messenger*.

Now Ready, in cloth, 16s.,
THE GARDENERS' CHRONICLE
VOLUME for JANUARY to JUNE, 1877.
W. RICHARDS, 41, Wellington Street, Strand, W.C.

NOTICE.—In consequence of the very small competition (3 bunches), and the bad condition in which Golden Queen was shown at the Crystal Palace, the Judges withheld the Prizes offered. We propose therefore to offer the same Prizes of £5, £2 and £1 for the best single bunch of Golden Queen; also, the same amount for the best single bunch of Mrs. Pearson, at one of the autumn shows next year, probably during September. Due notice of which will be given in these columns. J. R. PEARSON, Chilwell, Notts.

SPIRÆA (HOTEIA) JAPONICA.—The above can be had, in fine clumps for forcing, at 16s. per 100, £7 per 1000, or £60 per 10,000. J. VANDER SWAELMEN, Lily Nursery, Ghent, Belgium.

CHRISTMAS ROSES, 20,000, HEPATICA CÆRULEA, 8,000. May be had from J. VANDER SWAELMEN, Lily Nursery, Ghent, Belgium.

SPIGELIA MARYLANDICA.—Beautiful perennial, of gay appearance. Strong flowering plants, with many crowns, at 6s. per 100. J. VANDER SWAELMEN, Lily Nursery, Ghent, Belgium.

PANDANUS UTILIS.—Extensive stock of this splendid ornamental plant, at 20s. per 100, 180s. per 1000. Extremely healthy, 6, 8 and 10 inches high and upwards. J. VANDER SWAELMEN, Lily Nursery, Ghent, Belgium. N.B. English CATALOGUE post-free.

PROTHEROE AND MORRIS, HORTICULTURAL, MARKET GARDEN AND ESTATE AUCTIONEERS AND VALUERS, 98, Gracechurch Street, City, E. C., and at Leytonstone, E. Monthly Horticultural Register had on application.

Transit Agency for Plants, Seeds, &c.

White Cross Nurseries, Hereford.

IMPORTANT TO NURSERYMEN, SEEDSMEN, FLORISTS, and Others.

TO BE SOLD, by Private Treaty, as a going concern, in consequence of a Dissolution of Partnership, the whole of the valuable **STOCK-IN-TRADE**, with 2 Greenhouses, Propagating Houses, 2 Vineries, and 4 Ranges, about 500 feet in length, of Pits, fully stocked, and in good repair; Horse, Van, Spring and Heavy Carts, Tools, Implements, Utensils, and Plant, upon and belonging to the White Cross Nurseries, situated on the confines of the City of Hereford, together with the Stock of Agricultural and Garden Seeds, Fixtures and Effects at the Seed Warehouse, occupied in connection with the Nurseries, and situated in Library Buildings, Hereford, aforesaid. The Nurseries (with the Cottages and Buildings thereon) cover an area of about 23 acres, are well stocked with the choicest variety of every kind of Fruit, Standard and Dwarf Roses, and other Trees, Ornamental and other Shrubs, Plants, &c., are well and pleasantly situated, close to the City of Hereford, and within a few minutes' walk of the Barton Railway Station.

The Nurseries, together with about 12 acres of Pasture Land, are held under a Lease of which about 5 years are unexpired, and will be included in the purchase.

To view, apply to Mr. CHARLES WHITING, the Foreman at the Nurseries. Any further particulars which may be required may be obtained on application to H. C. BEDDOE, Esq., Hereford; or, Messrs. DEWES, SON and WILKS, of Coventry, Joint Solicitors.

Sealed Tenders (marked "Tender for White Cross Nurseries") to be forwarded to Mr. HENRY BERRICK, of Earl Street, Coventry, Public Accountant, not later than October 25 next. The Vendors do not bind themselves to accept the highest or any Tender.

To Nurserymen and Others.

TO BE DISPOSED OF, one of the oldest established **NURSERY BUSINESSES** in the North of England, with valuable connection.

The executors of the late Mr. John Harrison, of the North of England Nurseries, Catterick Bridge and Scorton, are open to treat with a gentleman possessing capital, for the disposal of the business, which has an established connection of nearly 50 years. The Nurseries consist of about 60 acres of Freehold Land, about 40 acres of which are stocked with a choice Collection of Roses and General Nursery Stock. There are good Residences in the Grounds, and fine Ranges of Glass, close to the Catterick Bridge Station of the North-Eastern Railway, situate between Darlington and Richmond, and offering unusual facilities for doing a large and profitable business. A large portion of the purchase money could remain on security of the property at a reasonable rate of interest. Possession could be given at any time as going concern. Principals or their Solicitors only may apply to the undersigned. A. E. HARRISON, Solicitor, Church Yard, Rotherham.

Capital Farm of 186 Acres,

TO BE LET, from Michaelmas, within 14 miles of London, and 2 miles from a Station. About 40 Acres are in Grass, the rest Arable, equally suitable for Corn or Root Crops, and a portion would carry Sheep well. It is also admirably adapted, both by soil and situation, for Market Garden Purposes. Comfortable House and roomy Buildings.

Apply to Messrs. DEBENHAM, TEWSON and FARMER, 80, Cheapside, E.C. (24,758).

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

NOTICE is hereby given that an Addition to the LIST of **PENSIONERS** of this Institution will be made in January next. All persons desirous of becoming Candidates are required to send in their applications to the Committee, on or before November 5 next, after which day they will not be received. Preference will be given to those Applicants who have been Subscribers for fifteen years and upwards. Should there not be sufficient Applicants of that class then the claims of those who have not subscribed so long, or not at all, will be considered.

By order, EDWARD R. CUTLER, Secretary.

14, Tavistock Row, W.C.—October 5, 1877.

Printed Forms of Application may be obtained from the Secretary.

THE IMPROVEMENT OF LANDED ESTATES, By DRAINAGE, ENCLOSING, CLEARING, THE ERECTION OF FARM BUILDINGS and COTTAGES, WATER SUPPLY, &c.

The Land Loan and Enfranchisement Co.

(Incorporated by Special Act of Parliament)

ADVANCES MONEY.

1st.—To the **OWNERS of SETTLED and OTHER ESTATES**, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing, and General Improvement of Landed Property in any part of the United Kingdom.

2d.—To the **OWNERS of SETTLED ESTATES in ENGLAND**, for the Erection or Completion of Mansions, Stables, and Outbuildings, and for the Construction or Erection of Reservoirs, and other Works of a permanent nature, to supply water for the Estate, or for any other purpose.

3d.—To **LANDOWNERS** generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.

4th.—To **INCUMBENTS**, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.

5th.—To **COPYHOLDERS**, for the Enfranchisement of Copyhold Lands.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years.

No Investigation of the Landowner's Title is necessary. Forms of application, and all further particulars may be obtained of

Messrs. RAWLANCE and SQUAREY, 22, Great George Street, Westminster, S.W.; of Messrs. ASHURST, MORRIS, CRISP, and CO., 6, Old Jewry, London, E.C.; of Messrs. GILLESPIE and PATERSON, W.S., 87a, George Street, Edinburgh. Agents for the Company in Scotland; and at the Offices of the Company, as below.

T. PAIN, Managing Director. EDWIN GARROD, Secretary. Land Loan and Enfranchisement Company, 22, Great George Street, Westminster, S.W.

WM. LEWIS GOAD (Messrs. Fraser, Goad & Co.), respectfully informs his numerous Friends that he has resumed Business on his own account, as a **WHOLESALE and RETAIL SEED MERCHANT**, at 7, Borough Market, London, S.E., and trusts that the kind support given to him for so many years will be extended to him in the future, as it will be his constant endeavour to merit a renewal of the confidence hitherto reposed in him.

From Mr. H. BENNETT, *Belle Vue Crescent, Clifton, Bristol.* March 10, 1877.

"I am glad to tell you that the Hyacinths, Tulips, and Crocus I had in the Autumn have given entire satisfaction; the flowers are splendid."

From R. PRONYER, Esq., *Rathgate, N.B.* February 7, 1877.

"The Bulbs received from you in the Autumn have been particularly fine; some of the Hyacinths and Tulips now in bloom are large and beautiful, and have far exceeded any that I have had before."

DANIELS BROS., THE QUEEN'S SEEDSMEN, NORWICH.

Alnwick Seedling Grape Vine.
D. P. BELL begs to offer young plants of the above Vine, the true variety as grown at Clive House, from which the only exhibit has been made, and for which he received the First-Class Certificate from the Fruit Committee of the Royal Horticultural Society, December 6, 1876, regarding which the report of the Committee, as given by the *Journal of Horticulture*, is as follows:—"The bunch is large and heavily shouldered, with a stout stalk. The berry stalks are stout, and the berries large and roundish oval, frequently with natural furrows, skin quite black and membranous, covered with a fine bloom; flesh firm, tender, very juicy, and sweet. It was unanimously awarded a First-Class Certificate. This is a far superior fruit to Alicante, and will no doubt prove to be a late-keeping variety of great value." It is important that the public should know that this, the only certificated variety (and therefore the original), has been exclusively raised at Clive House, and cannot be had elsewhere. Plants 15s. each.
 The fruit now hanging on the parent Vine may be seen on application.

To the Trade.
W. HEATH and SON beg to offer the undermentioned plants, all of which are healthy and well-established:—

 A. M. C. JONGKINDT CONINCK, Tottenham Nurseries, Delfensvaart, near Zwolle, Netherland.

Planting Season.

E. BURGESS begs to offer the following:— E. Strong Standard and Pyramid PEARS, ROSES, Evergreen and Deciduous Flowering SHRUBS, English OAK, ELMS, and LIMES, up to 10 feet; LARCH and Spruce FIRS. Prices on application. The Nurseries, London Road, Cheltenham.

Vines—Vines—Vines.

B. S. WILLIAMS begs to announce that his VINES this year are in unusually fine condition, and are now ready for distribution.

NEW LATE-KEEPING BLACK GRAPPE, "ALNWICK SEEDLING."—This Grape was exhibited before the Fruit Committee, South Kensington, February 6, 1876, under the name of Clive House Seedling, a name the Committee have since thought fit to alter. The following is the description given by the Fruit Committee:—"It is a seedling between the Black Morocco and an unnamed variety raised at Wortley. The bunch shown was of fair size and well shouldered, and the berries large, oval in form, and jet black in colour, with a thick skin. The flavour was decidedly good, partaking of the rich sparkling flavour of the Black Morocco, but much sweeter. It has kept well till February, and will, no doubt, keep longer and prove a better Grape for general cultivation than the Black Alicante." This has been awarded a First-class Certificate. The stock offered is from the original plant. Early orders are respectfully solicited, as the stock is limited. Price 21s. and 42s. each. For Detailed List see BULB CATALOGUE.

NEW FIG, "HARDY PROLIFIC."—The fruit of this hardy Fig is about the medium size, Pear-shaped, rather tapering towards the stalk. The flesh is very sweet and luscious. It was introduced from France some few years ago, and has proved itself perfectly hardy. It must become a general favourite, as it is a very abundant bearer, either in pots or in a cold house, as well as on an open wall. It also ripens earlier than any other variety we know of. Price 10s. 6d. each. Extra sized fruiting plants, 21s. each.

B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London, N.

AMIES' CHEMICAL MANURE.

USED BY THE ROYAL HORTICULTURAL AND BOTANIC SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.

PREPARED IN A FINE, DRY, INODOROUS POWDER.

Price, £12 per Ton; 15s. per Cwt.; and in Canisters, 1s., 2s. and 4s. each.

Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to AMIES' CHEMICAL MANURE CO. (LIMITED), 79, MARK LANE, LONDON, E.C.

B G L OILCAKES.

ARREST YOUR PURCHASE of all other Cake until you have read the "Book of Testimonials" from users of this cake. Sent post-free by the Agent for the County, or by the Makers. Mills, Shad Thames, London, S.E.

And may be had by Order of all Booksellers and Newsmen.

Rosher's Garden Edging Tiles.

THE ABOVE and many other PATTERNS
are made in materials of great durability. The
plainer sorts are specially
suited for KITCHEN
GARDENS, as they
harbour no Slugs or Insects,
take up little room, and,
once put down, incur no
further labour or expense,

as do "crown" Edgings, consequently being much cheaper.
GARDEN VASES, FOUNTAINS, &c., in Artificial Stone,
very durable and of superior finish, and in great variety of design.
F. ROSHER AND CO., Manufacturers, Upper Ground
Street, Blackfriars, S.E.; King's Road, Chelsea, S.W.;
Kingsland Road, E.

Agents for LOOKER'S PATENT "ACME FRAMES,"
PLANT COVERS and PROPAGATING BOXES; also
for FOXLEY'S PATENT BEADED GARDEN WALL
BRICKS.

Illustrated Price Lists free by Post. The Trade supplied.

ORNAMENTAL PAVING TILES,
for Conservatories, Halls, Corridors, Balconies, &c.,
from 3s. per square yard upwards. Pattern Sheets, of plain or
more elaborate designs, with prices, sent for selection.

WHITE GLAZED TILES, for Lining Walls of Dairies,
Larders, Kitchen Ranges, Baths, &c. Grooved and other Stable
Paving of great durability, Wall Copings, Drain Pipes and Tiles
of all kinds. Roofing Tiles in great variety, Slates, Cement, &c.
F. ROSHER AND CO., Brick and Tile Merchants.
See addresses above.

SILVER SAND,
fine or coarse grain as desired. Prices by Post per Ton
or Truck-load, on Wharf in London, or delivered direct from
Pits to any Railway Station. Samples of Sand free by post.

KENT PEATS or LOAM supplied at lowest rates in any
quantities.

F. ROSHER AND CO.—Addresses see above.
N.B.—Orders promptly executed by Rail or to Wharves.
A liberal Discount to the Trade.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK
VARNISH for Preserving Ironwork, Wood, or Stone.
This Varnish is an excellent substitute for oil paint on all out-
door work, while it is fully two-thirds cheaper. It was intro-
duced upwards of thirty years ago by the advertisers, and its
genuine good quality, notwithstanding a host of unprincipled
imitators, is fully attested by its constantly increasing sale. It
may be applied by an ordinary labourer, requires no mixing or
thinning, and is used cold. It is used in the grounds at
Windsor Castle, Kew Gardens, and at the seats of many hun-
dreds of the Nobility and Gentry, from whom the most flattering
testimonials have been received, which HILL & SMITH will
forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon,
at the Manufactory, or 1s. 8d. per gallon carriage paid to any
Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.
"The Rylands, Alderley Edge, Manchester.—Messrs. Hill &
Smith.—Sirs,—For some 20 years I have used your 'Black
Varnish,' and shall be glad if you will forward me another cask,
as I consider it the best thing known for the preservation of all
outdoor work, either wood or iron, that requires to be painted.
—Yours respectfully, ALFRED LOWE, J.P."

Apply to HILL and SMITH, Brierley Hill Ironworks, near
Dudley; and 113, Queen Victoria Street, London, E.C., from
whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of
HILL & SMITH that spurious imitations of this Varnish are
being offered by unprincipled dealers at a slight reduction in
price, they would especially draw attention to the fact that every
cask of their Varnish is legibly marked with their name and
address, without which none is genuine.

CARSON'S' PAINT,

PATRONISED BY THE QUEEN,

**HYACINTHS IN POTS, GLASSES,
AND BEDS.**

IT is only those acquainted with the bulb trade that can have any idea of the immense quantity of Hyacinths annually imported from Holland, where their culture is made a speciality by the Dutch growers, and from whence they are sent to supply the English and other markets that keep up an ever increasing demand for them. This is not much to be wondered at when we take into consideration their great value as decorative plants, and the ease with which they may be grown either with or without soil in dwellings in smoky towns or cities, or in beds or borders, for either of which purposes they are without rivals, coming in as they do in mid-winter or spring, when there are so few flowers to cheer and enliven.

The first to greet us is the small Roman, that may be had in bloom by the middle of November and from that time onward, provided bulbs are obtained at once and potted successively, and grown on gradually till they are sufficiently rooted for forcing. Owing to their small size they may be potted almost as thick as Crocuses, as they require but little soil, their capacity for flowering depending more on the strength already stored up in them than on any benefit they derive from the material their roots have to feed on. This is the case with the larger varieties, and therefore to obtain fine spikes it is necessary to get heavy well-matured bulbs, and to secure these orders should not be delayed, as first-comers are supposed to get the pick, although some growers hold a contrary opinion, thinking that the best and soundest bulbs are held back, as only such will keep plump for any length of time. Be this as it may, certain it is that any advantages gained that way are more than counterbalanced by not having them potted early so as to get them well rooted and allowed to come slowly on. In potting the small Roman variety already alluded to, as many as six or seven may be put in a 32 sized pot, and if placed regularly at equal distances apart they will make a fine display, and be most valuable for standing in windows, or affording cut flowers, a purpose for which they are particularly suited.

In cultivating the large Dutch kinds for conservatory or room decoration, I would much rather have them three in a pot, than singly in the way they are usually grown, as the effect is far better, and a greater variety of colour may be had in a given space, as distinct shades may be associated together according to taste. Any one who has once seen them grown in this way will never be satisfied with the comparatively meagre display single plants make where the pots are generally quite disproportioned to the size of the plants and the head of bloom they carry. Seeing that the embryo spikes of these are already formed in the bulb, and only require further slight assistance to develop the same, very little soil is necessary, and therefore the pots need in no case be larger than 4 or 5-inch for the one bulb, and 6 or 7-inch when it is desired to have three together. These should be placed triangularly close round the sides, and in potting the quickest and best way is to loosely fill the pots with snail, and having put a pinch of sand for

the base of the bulbs to rest on, to keep them from coming into immediate contact with any earthy or manurial matter, the next thing is to press them sufficiently low down, that when finished off only just the crown of each is visible. Should new pots be used for the purpose they ought, first of all, to be soaked in water for some time, otherwise the tips of the roots die when they come in contact with the sides, owing to some deleterious salts evolved, or chemical action that takes place during the process of burning.

The soil best adapted for growing Hyacinths is a good turfy loam that has been laid up for a time so as to become mellow, and this should be chopped up and used in a tolerably rough state, and not sifted, as is frequently done, the small nodules being a great help in encouraging a free and healthy root action and ensuring proper porosity. As the space in the above sized pots will be small, it will be well to enrich the loam by adding about one-fourth of thoroughly decomposed cow-manure and a little leaf-soil and sharp sand, to prevent the whole from binding together. In a general way pots are frequently over-drained, and this should be avoided in growing Hyacinths by placing only one large crock to cover the hole, and on this a handful of the roughest soil, filling up with the other just as it comes. By doing this loosely, as before adverted to, the bulbs can be pressed in to about two-thirds of their depth and potted much more expeditiously and firmly than they can in any other way. It frequently occurs that when Hyacinths are purchased there are small offsets or loose particles around their base, and these should be removed before potting, or they act as robbers, or cause decay to set in.

Having completed the potting, the next thing is to stand them on a good hard bottom of coal ashes, or other material impervious to worms, and, this done, to give them a thorough watering through a fine-rosed pot, after which they should be allowed to stand for a few hours to drain and then be covered over to a depth of 6 inches or so with some old tan, half decomposed leaves, or anything of that kind. So favoured that at once begin to emit roots, and when the pots are full of these, and the bulbs have made a little top growth, it is time to remove them to some light cool pit or shelf in a greenhouse, from whence they can be drafted for forcing, or allowed to remain to come slowly on. It should be borne in mind, however, that the transition from being buried under the plunging material and their exposure to sun and light should not be too sudden, as in their then blanched state the tips of the leaves are apt to become injured, and when this takes place they are much weakened, and their beauty considerably marred.

In forcing it is best to begin with a low temperature, and to gradually increase the same from 50° or so by night to 55° or 60°, allowing a further rise by day of about 10° more, by which treatment they will come sturdy and strong. To encourage free growth the syringe should be well plied so as to wet them thoroughly overhead, and at this stage they will be much benefited by liberal supplies of liquid manure, which should always be given whenever they require water at the root. The great weight of the spike of bloom renders early support necessary, and the neatest way to afford this is to use pieces of small wire about 1 foot long made sharp at one end to thrust into the bulb close to the flower stem, to which it can then be tied. This may appear rather barbarous, but it will not do the least harm, and even if it did, as Hyacinths are generally discarded after blooming, it would not much matter. This is a waste, however, that ought to be avoided, for if the bulbs were taken care of and kept watered till their foliage died away naturally, they would be valuable for beds or borders, and ultimately

become as strong and good as those generally sold for such purposes. To come in late in the spring, another potting should be made a month or so hence and treated in the same way as those already touched on till they require light and air, when any cold frame or pit will suit their requirements. In such situations they do best plunged in leaves or moss, which keeps them in a state of uniformity as regards both heat and moisture, and this is a consideration when fine heads of bloom are desired.

There are probably quite as many or more grown in glasses as pots, and for this purpose the heaviest and best of the bulbs should be selected. Tye's Hyacinth glasses are perhaps the most ornamental and suitable, but any will do, and whichever are used should be filled sufficiently full with clear soft water for the bottom of the bulb just to touch it but no more, or they will be likely to rot. This done, the best place to stand them in is any cool dark cupboard or cellar, where they should be allowed to remain till the roots attain a length of 3 or 4 inches, when it will be time to remove them by degrees to some light airy position. In dwellings they cannot well be placed too close to the glass, as from want of air they have a tendency to become drawn, especially when the room is kept warm; and the coolest place they can occupy at such times is where they are almost touching the panes. It sometimes occurs that the water becomes fetid and offensive through standing, and when this is the case it should be changed for fresh, always using such as is pure and soft, but if a few small pieces of charcoal are put in at starting it will keep sweet much longer than without it.

All the attention they require is to keep the glasses filled up as the water evaporates or becomes absorbed by the plants, and when frosty nights occur to remove them from the windows to some safe position in the room, to be replaced again in their former situations the following morning. So managed they afford much pleasure and interest from day to day in watching their progress up to their final development—a time when they become doubly attractive and scent the air with the delicious perfume they exhale.

For growing in glasses the middle or end of October is quite soon enough to start the bulbs, and choice should be made of the single varieties, these being of a stronger and more robust constitution than the doubles, and even more beautiful, owing to the individual flowers not being so crowded and of a more symmetrical form.

In preparing beds for Hyacinths it is necessary to trench or break them up to a good depth, and in doing this to work in plenty of leaf-soil, old spent hotbed manure and road scrapings, or sharp sand, to secure a free and natural drainage during the winter, so as to preserve the bulbs in a sound healthy condition. Hyacinths look best in circular rows of decided colours or groups of one kind, and in planting they should be put in from 4 to 6 inches deep, and have a little sand scattered over them before being covered with the soil. To ward off frost during severe weather the buds will require some protection; the neatest and best material for the purpose is either cocoa-nut fibre or half-decomposed leaves, neither of which are at all objectionable in appearance or likely to be disturbed by wind in the way any littery matter would.

As a carpeting for the ground to take off its bare appearance in early spring, when the bulbs are coming into flower, a few golden Pyrethrums, or Thyme, have a good effect, and enhance the beauty of the Hyacinth by the contrast they afford. *J. S.*

TRADE MEMORANDUM.

ENQUIRIES have reached us as to a nurseryman near Kidderminster, signing himself J. Jackson. Is he the same person as H. Jackson, or William Jackson, who writes from the same place?

New Garden Plants.

LÆLIA SEDENI, nov. hybr. (*Cattleya violacea* superba × *Lælia devoniensis*)*.

Crossing may be done in different ways. The one grower crosses only to get a mule without the least idea to improve one plant by the good qualities of the other, provided there is hope of getting a new mule; another grower will make his endeavours the consequence of profound meditations, and will cross with the hope of getting something new, and better perhaps, than what we have, at least for certain qualities. The good horse-mule is far superior to both his parents in steady strength and the facility of bearing the coldest Highland showers. Thus, if we had a *Vanda* with scarlet flowers, such a meditating grower would cross it with *V. cœrulea* in the certain expectation of getting a new mule of light violet tint. It was decidedly an excellent idea of Mr. Seden, of the Royal Exotic Nursery of Messrs. Veitch, to cross the splendid old *C. violacea* (superba)—that combines brilliancy of colour and sweetness of smell with the bad habit of seldom succeeding well in our European stoves—with the free growing, free flowering tall *Lælia devoniensis*.

The lucky result of this cross is a free-growing tall plant, nearly like the old, now rather well-known *Lælia devoniensis*, having at the same time the brilliant warm tints of the flowers of *Cattleya superba*. The sepals and petals are of a very strong lilac, and the anterior part of the lip has that glorious deep purple which is the pride of the *Oponopodol*, or *Ducksmouth*, or *Masamo*. The chief part of the residuous part of the lip is white, the side lacinia rosy, with a purplish apex, and a deep brownish purplish bar extends from the base of the anterior lacinia to the very base of the lip. The column is white with purplish edges, and purplish tint at the front side. It is decidedly a very recommendable plant.

May I be allowed to add once more a few words about my calling the plant a *Lælia*. It has, indeed, only four pollen masses, as a *Cattleya*, but they are attached on both sides to the caudicle, and have a certain structure, that proves they would like to be split; and I have, indeed, observed such pollinia to be divided in two, as one might have suggested before. In *Cattleyas* the caudicle (strap) is never adherent on both sides to the pollinium, but one side is free, and thus it is in all the *Epidendrums* you may look to, the more so as, botanically speaking, there is no difference between the *Encyclia* section of *Epidendrum* and *Cattleyas*. Increase a flower of *Epidendrum Can-dollei* by six diameters, and show the representation to any of the British Orchidists, what will they say? "Oh, indeed—a new *Cattleya*." The *Lælia elegans* (*Cattleya elegans* of Morren the elder) has always such pollinaria with straps adherent on each side, and very often two pollinia on each strap. The *Cattleya devoniensis* is a very curious product, since it is very much like *Lælia elegans*; I even would regard it the same, if it was not said to descend from *Lælia crispata* and *Cattleya guttata*, when there is—at least of our actual knowledge—at the natal place of *Lælia elegans* no *Lælia crispata* to be seen, and no *Cattleya guttata*, but the next cousins, *Lælia purpurata* and *Cattleya guttata* Leopoldi. It is much to be wished that Mr. Seden may soon raise magnificent hybrids by crossing the two last plants, the more so within my knowledge the demand for *Lælia elegans* is far greater than can be supplied by the English growers. *H. G. Rehb. f.*

MONTBRETIA POTTSHI, Baker, n. sp. †

This is one of the most valuable additions that has been made for a long time to our stock of hardy Cape bulbs. It flowers in August, and was introduced by Mr. G. H. Potts, of Lasswade, near Edinburgh. In popular language the genus *Montbretia* may be defined as consisting of those Irids which possess the habit and small scarious spathe-valves of *Ixia*, in combination with the irregular funnel-shaped perianth and parallel unilateral stamens of *Gladiolus*. For a *Montbretia* the present plant is unusually large, as it reaches a height of 3 or 4 feet. The individual flowers are about the same size as in the short-tubed species of *Montbretia* already known, such as *securigera* and *lineata*. In colour they remind one most of those of *Tritonia* (*Crocasma*) *aurea*, *Botanical Magazine*, t. 4335, being a bright deep yellow, tinted on the outside with red. These *Montbretias* are amongst the least fugacious in their flowers of all the *Iridaceæ*,

* *Lælia Sedeni*, nov. hybr.—Habitus, caule foliis *Lælia devoniensis*, inflorescentia pluriflora; sepalis ligulatis acuminatis; tepalibus oblongis acutis; labello trifido; lacinia lateralibus antorsis triangulis; lacinia media cuneato oblonga emarginata denticulata crispata; columna clavata trigona abbreviata.—*Cattleya violacea* (superba) × *Lælia devoniensis*. *H. G. Rehb. f.*

† *Montbretia Pottshi*, Baker, n. sp.—Rhizomate repente filiformi, bulbis globosis, caule 3-4-pedali dimidio superior ramoso; foliis 5-6 distichis glabris linearis-ensiformibus, modice firmis, panicula laxissime ramis ascendentibus laxè aquilalateraliter spicatis; spathe valvis parvis integris vel apice emarginatis interne viridibus superne rubellis scariosis exteriori lanceolata interiori oblonga; perianthii infundibularis fulvi segmentis oblongis obtusis subæqualibus, tubo medio ciliato ampliato dimidio brevioribus, genitalibus inclusis.—*Gladiolus Pottshi*, M'Nab, in *Hort. Edin.*

and as the present plant bears four or five gradually centripetal spikes of twelve to twenty flowers each, it keeps in flower over a long time. Mr. M'Nab has cultivated it successfully on his rockeries at Edinburgh, and distributed it under the name above cited. For the specimen from which the present description was drawn up I am indebted to Max Leichtlin, Esq., who has grown it in the open air at Baden-Baden. Altogether I venture to predict with confidence that it will become a popular favourite.

Bolbs globose, connected by a thread-like rhizome. Stem 3-4 feet long, including the inflorescence, which reaches about half way down. Leaves about four in a distichous rosette at the base of the stem, and two others higher up, below the inflorescence, linear-ensiform, moderately firm in texture, green, glabrous, reaching a length of 1½-2 feet, and a breadth of ½-¾ inch. Panicle 1½ foot long, consisting of 3-4 lateral branches in addition to the end one, the lower ones subtended by reduced leaves half a foot long. Spikes 6-9 inches long, equilateral, 2 inches broad when expanded, 12-20 flowered. Spathe-valves ½ inch long, entire, or faintly emarginate at the tip, green in the lower part, purplish and scarious in the upper half, the outer valve lanceolate, the inner oblong. Ovary green, oblong, ½ inch long. Perianth funnel-shaped, an inch long, deep bright yellow on the outside flushed with brick-red, the sub-equal oblong obtuse segments about half as long as the tube, which is cylindrical at the base, without any calli, dilated suddenly at the middle, especially on the upper side, to a diameter of ⅓ inch at the throat, genitalia included. Stamens unilateral, inserted half way up the tube; filaments filiform, bright yellow, ⅓ inch long; anthers linear-oblong, basifixed, the same colour as the stamens. Style protruded from the perianth, with three branches ½ inch long, which are entire and cuneate at the tip and stigmatose round the outer edge. *F. G. Baker.*

DOMESTIC FERNERIES, MOVABLE AND FIXED.

UNDER this heading we include all kinds of arrangements for growing Ferns and other plants which do well under similar treatment, either in the rooms of dwelling-houses or attached to the outside of windows, and attended to from the rooms. The simplest form of fernery is that of a bell-glass placed over a plant growing in a pot or shallow pan; and this plan of cultivating each kind separately has many admirers amongst true lovers of plants, inasmuch as it admits of varying the management to an unlimited extent. But the space taken up by even a small collection grown in this way is so great that few can afford it

dwarf kinds are soon killed by the stronger-growing species, and the effect of the original arrangement is completely lost. But when a selection of slow-growing plants is properly made, and when they are properly planted, with room enough between for the development of every plant, and with the surface of

to allude here to the heated propagating cases of Messrs. Barr & Sugden, which have enabled amateurs to strike cuttings of very many plants which without their assistance they would not have succeeded in growing.

Amongst window ferneries we have seen few better than those in the coffee-room at the City of London Club, near the Bank of England (see pp. 428, 429); of these we are able to furnish engravings from photographs taken some time ago by Mr. Arthur E. Smith. The room is 60 feet long, 30 feet broad, and 30 feet high, and at each end there is a central mantelpiece, with a large mirror over it, and a window upon either side of the fireplace. The lower half of these four windows opens into a miniature conservatory of foliage-plants, and a different appearance is presented by each of them. One end of the room is shown in fig. 83, where in the mirror is seen a reflection of the opposite end of the room. The handles seen above the ferneries indicate that the lower sash has been thrown up to its highest point.

Each window-sash is 4 feet 6 inches wide by 5 feet high; but this does not indicate the size of the ferneries, which are 8 feet wide, and 7 feet high near the window-pane, with a glass roof sloping off to 6 feet in height at the back. They are 4 feet deep.

We are careful in giving these dimensions, because window conservatories are too often constructed of just the same width as the window, and with the bottom on the same level with the window-sill. In those here figured the space for growing Ferns extends for more than 18 inches on either side of the window, so that large plants can then be used, and portions only of them contribute to the general effect in the room—an important advantage, which could not be otherwise obtained. Again, the depth of the fernery below the window-sill is another great advantage, since it permits the use of much taller plants than could otherwise be employed.

One of the ferneries has on its right a series of pocket-like pools on the face of the rocks, with a stream trickling down from one pool to another until it is lost amongst the plants growing at the bottom. This trickling is not seen unless the observer is close to the left side of the window; but a reflection of it is seen in a good-sized mirror placed diagonally across the further left angle of the case, apparently at the end of a deep cave, the edges of the reflecting glass being concealed amongst the rockwork, which is covered with Ferns.

Another has for its central object a fine young plant

FIG. 82.—MOVABLE FERN CASE.

the soil hidden by some small species of Selaginella or Ficus, such a case becomes and long remains an object of beauty and interest, as may be seen in the engraving (fig. 82).

Great improvements have of late years been made in these movable ferneries, both in the convenience of access to the growing plants, in the means of regulat-

FIG. 83.—WINDOW FERNERIES AT THE CITY OF LONDON CLUB.

in rooms. Hence the more frequent employment of larger pans or cases capable of containing several species which are thus grown without taking up much space in a room, while they afford the pleasure of seeing the contrasts and harmonies between different forms and shades of foliage when judiciously selected. These cases are too often crowded with as many plants as can be crammed in, without allowing space for the plants to grow, and as a natural result the

ing the ventilation, and in heating them when necessary. The last-mentioned aid to healthy growth is sometimes attained by pouring hot water into a receptacle below and around the soil, and sometimes by suspending a small lamp under the water-tank, the degree of heat necessary being regulated by the size of the flame and its distance from the water which it has to heat.

In connection with this it will not be out of place

of Cibotium princeps, under the gracefully arching fronds of which a little fountain mimics the curves of the Fern above. In this fernery two pieces of reflecting glass are inserted amongst the rockwork at the back, one on the extreme right, the other on the extreme left, the result of which arrangement is that the sides of the fernery are repeated, and that the fernery appears to be twice as deep as it really is.

The third has a deep aquarium, through which a

stream of fresh water flows, entering below and overflowing into a cavern on one side. The rockwork is here arranged so as to carry out the leading idea of a large pool, the surplus water of which descends into another pool which is out of sight, and the contents of the upper pool are rendered visible through a sheet of stout plate glass on the side nearest to the window.

The fourth has a dashing cascade just in front of the spectator, the water falling upon a shallow ledge of rocks, which causes a greater splash than if it fell into a pool. There is much less light in the last two cases than in the others, owing to the nearer proximity of tall buildings, and consequently the foliage is neither so varied nor so luxuriant. This drawback is, however, overcome by using here a preponderance of such plants as have been found to do best under those unfavourable conditions.

It will have been noticed that, in all the four, water plays a not unimportant part, and, particularly in the hot weather, conveys to both the ear and the eye a more refreshing feeling of coolness than foliage alone could impart.

These ferneries are provided with ventilators above and below, and are heated during the colder months with two flow and one return pipes of 2 inches diameter, with means of regulating the heat in each at will. A cold-water pipe is carried for some distance along by the sides of the flow-and-return pipes, and is connected with a screw-nozzled tap in each case. When the plants require syringing or watering, a piece of flexible tube, with a rose at the other end, is screwed on to the tap, and water with the chill off is thus at command.

The ferneries have their bottoms composed of slabs of slate 2 inches thick, which are supported each upon three strong iron brackets fastened to the external walls. The three sides of the ferneries are partly slate and partly glass, the lower 3 feet being of inch slate mortised at the angles.

The rockwork is built of brick burrs below and rough bark above; the former (of which three cart-loads were used) is fixed with Portland cement, and the latter is fastened with copper-wire. This portion of the work was entrusted to Mr. Alexander Blake, of Fulham, whose skill in copying natural rockwork with such materials is well known. Mr. Blake also supplied and planted all the Ferns, Palms, and other plants.

Palms appear to do equally well in all the cases, especially species of *Seaforthia*, *Latania*, *Areca*, *Geonoma*, &c. These, with *Aspidistra lurida variegata*, *Ficus elastica*, *Dracenas*, and a few other things, form the leafy decoration of the two more gloomy cases, the climbing Fig growing well, and the Japan *Lygodium* hanging in bunches from the wires attached to the roof. In the lighter cases there is more variety, the climbing Fig hanging in graceful festoons, while *Begonias*, *Marantas*, *Anthuriums*, *Cyperus*, and numerous Ferns, together with many of the plants previously mentioned, look quite happy.

As the effects described are the result of plants put in four years ago, we are not premature in pronouncing the arrangement to be a great success, and we can well imagine the relief which the jaded man of business must derive from partaking of his basty luncheon under such influences.

For much of the foregoing information we are indebted to Mr. W. Thomson, under whose superintendence these ferneries were constructed and furnished, and who merits warm commendation for the taste with which he has managed to bring a sub-tropical garden into each of the four corners of a London club-room.

THE CULTIVATION OF THE ROSE.*

I SHALL in this paper endeavour to describe clearly some of those essential items of culture most calculated to ensure a fair measure of success.

Although the Rose possesses charms which enchant the senses more than any other flower, it is, on the whole, void of some desirable qualities found in other genera of less pretensions, that is to say, the habit of the Rose forbids its combination with other plants with good effect; even in such gay company as scarlet *Pelargoniums* and *Calceolarias* it neither looks dignified, nor heightens the appearance of its neighbours. It is in groups alone and in the pure Rose garden that its supreme beauty is displayed to advantage.

PROPAGATION BY CUTTINGS.

With many others I prefer this mode of propagation for dwarf plantations, which are, as a rule, pegged

* Read at a Meeting of the Scottish Horticultural Association, by Mr. A. Kerr.

down near to the surface of the soil. Plants on their own roots can be handled with more freedom, and they will not trouble the cultivator by starting up "rogues" or stock shoots, as budded plants so frequently do. Roses will root freely if operated upon in the months of September and October by selecting well-matured growths. Such growths ought to be carefully chosen, with an eye to preserving a uniform number of growths on the plant left, while those detached ought to have a small portion of the previous year's growth, which is known in the profession as "heel." In forming the cuttings, the operator has first to cut off with a keen-edged knife a portion of this old wood intended to form a "heel," leaving about one-eighth of an inch for that purpose. The cuttings are then shortened back to 8 or 10 inches by taking off their tops, thus making them ready for insertion.

In some localities cuttings root readily without the aid of protection, if planted at the bottom of a wall in a sunny part of the garden, and the weather prove favourable; but under all circumstances that process is assisted by a covering of glass. More especially is this protection essential where the place is cold, with a damp, adhesive soil, and the quantity of cuttings limited. Seeing the risk of diminishing the number is great in a cold, open aspect, it is preferable to form a comfortable bed for their reception under a glass frame or hand-glass. The bed ought to be 9 inches deep, composed of light, fresh loam, river sand, and leaf-mould, the last ingredients in equal proportions, while the loam should be present in greater quantities. Moderately beat the bed to a rather firm consistency, so that the cuttings are held secure after being inserted. Plant the cuttings in lines 8 inches apart, and 2 inches between the plants, inserting them so that three eyes are exposed above-ground. Carefully tramp the soil firmly around the cuttings as the work proceeds, and leave the surface trim and neat, after which give a moderate watering over the whole, and cover with the glass frame. Ventilate moderately daily, and shade when the sun shines strongly, but not otherwise.

Nothing further need be said regarding the attention required, excepting that a couple of mats should be used to protect them from severe frost, but on no consideration should they be kept covered in the absence of frost. With such encouragement most of the cuttings will root, but Tea-scented and some of the Bourbon varieties are rather stubborn in that process. However, give them time; so long as their wood retains freshness, there is vitality in them.

Keep the soil free from weeds and moss; the latter is apt to accumulate when left undisturbed by the hoe. With the first indication of returning spring, allow a judicious quantity of water to be supplied by means of a pot provided with a rose. Keep the bed moist until the cuttings have assumed the character of plants, as indicated by their strength, or by the young shoots beginning to push. When it is ascertained by their growth that they are properly rooted, lift them carefully, and plant them at wider distances; shade from the sun, and keep rather close until their roots have retaken to the soil, when shading must be discontinued, and air admitted more freely. Ultimately, the sashes should be altogether removed.

PROPAGATION BY LAYERS.

This is a very successful method of increasing the stock of Roses, and may be effected with great ease with plants previously laid to the ground. The proper time to layer Roses is from June to the middle of July, but it is to their advantage to have it performed early, so that the layers get rooted before autumn is far advanced, else they will continue through the winter in the same state as they happen to be in the autumn.

For layering, first have the bed pointed a few inches deep with a digging fork; follow this up by sifting an inch of sharp sand over the surface. Next stir with a Dutch hoe, leaving the surface level. Have the required number of hooked pegs, and likewise a similar quantity of short stakes. Proceed then by selecting such shoots as are most convenient, choosing those which are neither too strong nor too weak, but which show a good bone of ripe wood, yet not too hard ripe. Bend the middle of the shoots to the ground with both extremities inclining upwards, then make an incision exactly at that part where the shoot touches the ground. Direct the knife upwards, making a clean cut up the centre about 2 inches long, then hollow out

the soil where this incision is intended to rest. Again bend the centre of the shoot, and cause the tongue of the slit thus formed to dip into the soil. Next fix it in position securely with a hooked peg, supporting the upper extremity by tying it to a stake, then to fill up the hollow made for the reception of the layer.

Three months after this operation most of those shoots ought to be rooted, when they may be separated from the mother plants, and potted into a loamy mixture, giving them the benefit of a cold frame for the succeeding winter. March is perhaps the best season of the year to have them turned out of their pots and transplanted where they are to form permanent plants.

PROPAGATION BY BUDDING.

This operation is at once an interesting and pleasing recreation, more especially to the amateur. To be an expert budder requires much practice—not that any material difficulty attends the performance of it, but what is demanded of the operator is care not to insert the knife too deeply while making the slit in the stock, causing damage to the wood and the thin layer of cambium, whose chief functions are to form new layers, heal up wounds, and form a union with the adopted bud or graft. This important formation is most sensitive to exposure to sun or wind, which causes it to brown and form a thin bark-like skin, making a union between it and the bud an impossibility.

Being furnished with the required materials, commence by cutting back all the leaves of the shoot that is to furnish buds; also displace the spines or prickles from both it and the stock. Having now determined where to plant your bud, make an upright cut about an inch long, penetrating the inner bark and no more. At the upper extremity of this incision make a horizontal cut; the thin edge of the knife-haft is carefully introduced between the bark and wood, entering it where the horizontal and longitudinal incisions unite, gently raising the bark and sliding the knife along at the same time. The opposite side of the bark incision is operated upon in the same way. Scooping out a sheath of bark containing a bud comes next to be considered. This ought to be performed by a single cut of the knife, inserting the knife about half an inch below the bud, guiding it inwards and upwards until the edge is opposite the bud, when the knife must take an outward course, sloping the cut at top into a similar form to the one below the bud. The extractor of the wood which fills the sheath of bark thus formed requires care to prevent extracting the core of the bud along with the wood; but to lessen this danger cut off the sheath with as thin a body of wood in it as possible, allowing sufficient margin of bark on each side of the bud. Remove the wood out of the sheath by an easy twitch. Having inserted the point of the knife between the bark and wood insert the bud by raising one side of the bark by means of the knife-haft and the thumb, placing the sheath parallel with the lengthened cut, then gently push in the sheath until the bud is neatly placed; the bark on the opposite side should be treated in a similar way. The bud adjusted, hold it in position with the thumb, draw the knife through the horizontal cut in the stock, cutting the upper portion of the sheath so that it fits exactly the cross cut in the stock, wrap up the bud with soft matting, being careful to cover the incision, and only allow the bud to peep out.

I shall not stay to inquire regarding the different "stocks" recommended by various authorities whose opinions are divided. Some incline to prefer the Manetti, but the great majority are disposed to favour the Dog Rose, which I consider, on the whole, preferable to all others for general budding. All stocks have a tendency to generate stock-shoots more or less, but the Manetti especially, and its excessive vigour of growth is objectionable. If restrained by having weak-growing Roses budded on it, it invariably starts stock-shoots, which, if not soon discovered, have a fatal effect upon the Rose, causing it to dwindle and die. Further, it takes a practised eye to distinguish it from the genuine Rose shoots when forming part of a mass of growths. The proper time to collect stocks of the Dog Rose is at the fall of the leaf. It is most important to cut away all useless protuberances on the roots, dressing them back to the last fibres rather than allow them to remain and produce stock-shoots. Plant in rows, after having previously trenched and manured the ground well. Cow manure in a moderately fresh condition should be preferred to all other

home manures, and it is desirable not to have too much of the manure in immediate contact with the roots; rather have the body of it near the bottom of the trench. The roots will find sufficient food for their immediate wants if a portion of this stimulant is incorporated with the soil. Plants intended to form standards may at once be cut back to the desired height, while those required for dwarfs must be cut back to 6 inches above the ground. In all probability the standards will furnish many growths up their stems; these should all be removed, excepting two or three selected for budding near the upper extremity. Budding ought to be done early in the summer, when it is found that the bark will rise freely, and the shoots from which the buds are taken are in a medium state of maturity. A sunless mild day is perhaps the best for this operation. Hot dry weather has a tendency to dry the opening on the stock in which the bud is deposited, and besides causes the sheath to shrink unless expertly performed.

About a month after budding, when union has been effected between bud and stock, have the wrappings cut, so that no interruption may be made to the swelling of the stems. All buds still dormant must continue to wear their wrappings until a union has been accomplished. In February following let there be a general pruning away of all rank growths on the stocks, cutting them back to a couple of eyes above the buds, which will afford great assistance to them in their first start, and will further materially assist the buds by allowing them to appropriate to their own use food offered through the reviving action of the roots, while at the same time an over copious rush of sap will be restrained by detaching the vigorous growth of the stocks, whose powerful agency proves more than enough for inactive buds. Ultimately let the remaining part of the shoots be cut off above the buds when the buds have started a few inches.

(To be continued.)

HARDY TREES AND SHRUBS.

UNDER the title of "Half-hours at Kew," two years ago, I contributed some notes, among other things, on the hardy Oaks and other deciduous and evergreen trees and shrubs. Since then many of the species and varieties in the plantations at Kew have considerably developed their characters, and I therefore propose adding to, or repeating, what I then said respecting certain species and varieties, and mentioning some forms that did not come under observation at that time. It is true that the winters of 1875-6 and 1876-7 were not so severe as to afford any test of the hardness of the doubtful subjects, and the peculiar nature of the soil where most of the new plantations have been made—in fact one might say of the whole gardens—is so favourable to the success of tender plants that not all of the same species will be hardy in all situations around London even. It is very dry and gravelly, consequently growth is never excessively luxuriant, and the wood ripens pretty well; and, what is equally important, the roots lie dry in winter. Unfortunately there is a reverse to this, for although there are many large trees at Kew and a few very fine ones, they die off very fast. Possibly the copious rains which have fallen during the last twelvemonths may arrest to some extent the widespread decay, of which there is now only too much evidence in the shape of dead and dying trees.

One particularly fine Oak, of much greater age apparently than the bulk of the trees, deserves notice. It is near the lake in the pleasure-grounds, at the end farthest from the Thames, and is still in tolerably vigorous health, although its trunk must be nearly or quite six feet in diameter breast high. Any one really fond of trees will find many others to interest him in the wilds of the pleasure-grounds, where there is a greater variety than most people are aware of. This takes us naturally to the consideration of some of the Oaks first. The number of species and varieties perfectly hardy in the climate of London is legion, but there are some which are far preferable to others, and there are many which nobody except those making collections would care to plant. And, again, there are others which cannot be bought, and exist in a cultivated state in botanic gardens only. All who are able should go to Kew and see for themselves what an immense variety of deciduous trees and shrubs there is to choose from, though very few nurserymen keep a large variety, because ninety-nine people out of every hundred will only purchase the familiar Elm, Poplar, Oak, Beech, &c.

EVERGREEN OAKS.

Among evergreen Oaks, for instance, we rarely see anything except the small-leaved varieties of *Quercus Ilex*, which are certainly very useful for planting in exposed situations and near the sea, but rather gloomy withal. *Q. glauca*, a Japanese evergreen Oak, is a very fine species, of shrubby habit at Kew, but growing to a tree of considerable size in the south of Japan. The leaves are thick and coriaceous, dark glossy green on the upper surface, and somewhat greyish or glaucous beneath, where the nerves are prominent, and from 4 to 6 inches long by about 1½ inch broad. This is a really distinct, and apparently quite hardy Oak; and it is not only distinct as an Oak, but possesses a habit and *facies* peculiarly its own. The leaves, though larger, as seen from above, are not unlike those of *Kalmia latifolia*. There are several other Japanese forms having the same general character. *Q. Ilex* var. *latifolia* is a shrubby form with large leaves, about 3½ inches long by 2½ inches broad, but like most of its kin it has rather dull dark green leaves. *Q. Ballota*, as it grows at Kew, is an exceedingly ornamental tree, with lanceolate-oblong or rotundate leaves, the broader ones 2 inches across and all more or less prickly on the margin. It is rather a fast grower, making shoots 12 to 18 inches long.

DECIDUOUS OAKS.

In the *Gardeners' Chronicle*, October 9, 1875, p. 455, and April 7, 1877, p. 440, I have enumerated, with descriptive remarks, a large number of the most striking varieties of *Q. Robur*, and the most noteworthy American species. I will repeat some of them here, and refer back to the places quoted for details. Among those most noteworthy of *Q. Robur* pedunculata are:—*taraxacifolia* and *filicifolia*, having elegantly cut and lobed leaves; *concordia*, with rich yellow foliage; and *Granbyana*, with reddish-purple acorns and inner bark. These all retain their special characters. An Oak called *Q. sessiliflora pannonica*, with handsome, deeply lobed, almost pinnate leaves, is particularly deserving of a second mention. [This is probably *Q. conferta*; see *Gardeners' Chronicle*, 1876, vol. v., p. 85, fig. 18. Eds.] A small plant of an evergreen Oak, labelled "Species from Japan," is a very handsome thing, having broad, nearly sessile leaves of a bright glossy green on both surfaces, and more or less prickly on the margin. Some of the leaves are between 2 and 3 inches across, and the young shoots and leaves are tinged with red. Altogether, this promises to be a very ornamental shrub or tree. A dwarf dense variety of *Q. coccifera*, of almost spherical growth, looks exactly like a miniature Holly, the leaves being those of the common Holly, but usually less than an inch long. Another, labelled *Q. mongolica*, is remarkable for the large size of its leaves, which are about a foot long and 6 inches across in the broadest part, gradually tapering towards the base to the very short petiole. The outline of the leaf is nearly obovate-lanceolate, and is deeply lobed, the lobes being broad and rounded, with rounded sinuses. I have only seen quite a young specimen of it, and it is possible that the foliage is not so fine in adult trees; but it will be remembered that the American, *Q. bicolor*, as a small tree, at least, has even larger leaves. *Q. nigra nobilis* has also fine bold foliage. *Q. lyrata* is a North American species, with obovate leaves lobed at the tip, and narrowed down to a cuneate base. A very pretty small-leaved Oak is named *Q. lutea macrocarpa*, and perhaps also *Q. Ehrenbergii*. It has slender ash-grey branches, oblong, convex, pale green leaves about 2½ inches long, prickly-toothed, and strongly waved at the margin. Among the very distinct American species I may again name the narrow-leaved *Q. aquatica*, which is not unlike the Olive tree in habit and foliage, but the latter is of a livelier hue; *Q. heterophylla*, which some botanists have regarded as a hybrid, is ranked as a distinct species by Dr. Engelmann (see *Gardeners' Chronicle*, August, 1876, p. 164), in his classification of the Oaks of the United States. It has slender glabrous yellowish-green branches something like a Willow, and the leaves are also glabrous and glossy. The latter vary very much in outline.

VARIETIES OF SPANISH CHESTNUT.

One of the most striking is called *heterophylla* dissecta. The peculiarity of this is that three or four of the terminal leaves are much longer than the others and very narrow. Some that I measured were

7 to 9 inches long by less than half an inch broad, and some of them are furnished with a few irregular scattered lobes. This curious variety is certainly worth growing, and it is a very conspicuous object in a plantation. A variety of the ordinary *Castanea vesca*, in which the leaves are slightly margined with white, is exceedingly chaste and pretty. Another, *foliis aureo-marginatis*, is equally attractive. There are also several varieties differing more or less in the size, form, tothing, and surface of the leaves. One of the best bears the appropriate name, *glaberrima*. This has bold, brilliant foliage, and ornamentally is far superior to the common state.

ALDERS.

These are not much in request for the embellishment of the garden or park, though there are some cut-leaved varieties which are very beautiful, and retain permanently their special characters. The now pretty well-known *Alnus glutinosa* var. *imperialis* is certainly one of the handsomest varieties of its kind; *Oxyacanthifolia* has pinnatifid leaves, resembling those of the Whitethorn, but in consequence of a constriction of the midrib the leaf is curled back from the tip. The variety *aurea* is one of the best of yellow-leaved shrubs, and *rubronervia* has not very decidedly red ribs and petioles. *A. cordifolia* is a very distinct species, of rapid and symmetrical growth, and having smooth and shining cordate leaves. For planting in islands on the margins of lakes and streams, and in damp places generally, the Alders are useful for mixing with Willows, &c.; but they do not absolutely require wet ground, thriving perfectly in deep, rich soil.

PRIVETS.

These most useful shrubs, from our native species to the most ornamental of the many fine forms introduced from China and Japan, are not planted so generally as their merits entitle them to be. *Ligustrum vulgare* makes a neat hedge in a short time, where a strong fence is not required; but it has the reputation of exhausting the soil in its vicinity. This character it enjoys in common with its near relative, the Ash tree, and it may deserve it to a certain extent, but it is certainly within control; on the other hand, most of the specimens of *Ligustrum* are very accommodating as regards soil and situation. *L. japonicum* is a very handsome evergreen shrub, attaining a height of 15 to 20 feet, or perhaps more, even in this country; its glossy dark green foliage, set off as it now is (beginning of September) by the large panicles of white flowers, is very effective. It is also a valuable shrub for sea-side planting, and, without disparagement to its congeners, it may be said to be the best of the genus. *L. coriaceum*, which has a denser habit and much thicker leaves, is probably a Japanese garden variety of *L. japonicum*. *L. lineare* has linear-lanceolate leaves 6 inches long, and *L. macrophyllum* is very much like *L. lucidum*, but the leaves are trough-shaped. Some of the variegated varieties of the species mentioned are very pretty, especially a silver-edged one of *L. japonicum*.

ELÆAGNUS AND ALLIES.

I have elsewhere more than once strongly advocated the claims of the Sea Buckthorn, *Hippophaë rhamnoides*, for a place in ornamental plantations, not only in the neighbourhood of the sea, but also inland, and particularly on poor gravelly soil, in which also the *Elæagnus* do well. I am not able to say much as to their behaviour in a stiff soil, but as far as my experience goes, the Sea Buckthorn does not thrive so well as in a gravelly or sandy soil. The European *Elæagnus angustifolia*, and the American *E. argentea*, or Silver Berry, are both very pretty, the latter especially; it is of shrubby habit and has glistening silvery leaves. The Japanese species, planted out in one of the beds near the winter garden, do not grow much in height, but spread from the root, covering a considerable space. The handsomest one is named *E. conferta variegata*. It has broad leaves variegated with yellow on the upper surface and silvery beneath. *E. reflexa* or *japonica* is less ornamental in the green-leaved variety, but there are some pretty variegations of it, and the under-surface of the leaf is brown. Here may be mentioned the aromatic *Myrica californica*, a shrub of moderate size with linear-lanceolate leaves about 3 inches long, and its more elegant congener *M. asplenifolia*, better known as *Comptonia asplenifolia*. The latter is deciduous, forming a round-topped shrub 4 or 5 feet high, and when healthy, as it is in this gravelly soil, it is very pretty, the form

and lobing of the leaves being very distinct from anything else.

SOME JAPANESE SHRUBS.

The species of *Zanthoxylon* mentioned in my former notes appear to be quite hardy at Kew. *Z. schinifolium* and *piperitum* seem to promise well as ornamental shrubs. *Clerodendron trichotomum* is flowering sparingly, and is by no means a showy or striking object, as it is said to be in its native country. It is described as a small ornamental shrub, bearing a profusion of purplish-red flowers in large terminal panicles. The flowers on the specimen at Kew are borne singly in the axils of the leaves, or only three or four together, and not conspicuously coloured, the corolla being white and the calyx dull red. This may be due to want of vigour, and under more favourable conditions it might deserve the praises travellers have bestowed upon it. On the other hand it is also likely that there are several varieties, and this the least ornamental. *Nandina domestica*, an evergreen shrub belonging to the Barberry family, and extensively cultivated in China and Japan, has elegant ternately compound leaves and terminal panicles of white flowers. Although hardy in the West, as well as the allied *Akebia quinata*, it is doubtful whether either of them will prove perfectly so in the climate of London. But the most conspicuous Japanese element lately noticeable was the great variety of splendid Clematis in full flower. These are of undoubted hardiness, and as they come in now when nearly all other climbers are past their flowering season, their value as decorative plants cannot be over-estimated. The flowering season of many of the large-flowered varieties is naturally of long duration, and with a little management one may obtain a succession of bloom for a longer period; and with a careful selection of species and varieties it is possible to have Clematises in flower from May to October. The Japanese Snowdrop tree, *Pterostyrax japonica*, suffers in a comparison with the North American *Halesia tetraptera*.

MISCELLANEOUS.

A very pretty cut-leaved variety of Beech, *Fagus sylvatica comptonicefolia*, is not commonly seen. The Chilean *Aristotelia Macqui variegata*, *Azara microphylla*, *crassifolia*, &c., are handsome shrubs. The latter are remarkable for their large leaf-like stipules, *Aralia spinosa* and *Tecoma radicans* are flowering freely; *Coriaria myrtifolia* and *Paliurus virgatus* are almost past flowering. Most of the plants named under this head are to be found in the new plantations near the Douglas Pine spar, where also are several *Cistineæ*; *Kitaibelia*, *Lavatera*, and other *Malvaceæ* are in flower now. *Macleaya cordata* is also in flower in the same place, and there are many curious and rare plants, which to see would amply repay a visit. *W. B. H.*

FRUIT TREE CULTURE AT NORTHAMPTON.

At the Billing Road Nurseries of Messrs. John Perkins & Sons, Northampton, the culture of fruit trees has long been a special feature; and not only are they grown extensively, but they are also grown well. This is not matter for surprise, because the best possible attention is given to the production of good plants.

The soil is a peculiar one, for a surface soil of a good generous loam, to the depth of 2 feet or so, rests upon a bed of ironstone, and fruit trees do well in it, and it can be worked at any time. Heavy rains soon pass away from the surface; and the soil being free and open, it does not cling, or become stiff in the wettest weather. There is, however, this disadvantage, that a long spell of drought would be somewhat severely felt, but the best remedial measure under such a visitation is to keep it well stirred on the surface with the hoe.

The extensive breaks of black and red Currants, and white Currants in less quantity, form one of the features of the nursery. There are about 50,000 black and red Currants, remarkably good three-year plants, and Gooseberries of the same age, and capital bushy plants too, in almost equal proportions.

Of Raspberries, which are also largely grown, the Northumberland Filbasket is one of the leading varieties. This is regarded as a great improvement on the Fastolf; it is a very free bearer, the fruit large and finely coloured. Mr. John Perkins states that it

does not suffer so severely during dry weather as the Fastolf, and it does not make wood so freely.

What is known as the Farleigh Prolific Damson, the old Kentish green variety, is the most extensively grown, worked on the Mussel stock, which is considered the best for all Plums, Apricots, &c. This Damson Mr. Perkins considers the best in cultivation, being a free bearer, having a good crop on young trees. It is not considered to differ from Mr. Rivers' Cluster or Crittenden Damson.

Apples are largely grown, worked on the Paradise stock to form pyramids and dwarf bush trees for small gardens, and on the Crab stock for standards. In the latter case only such sorts are worked as are likely to be profitable in this form, such as Lord Suffield, Blenheim Orange, Normanton Wonder, or Dumelow's Seedling, Cellini Pippin, Cox's Orange Pippin, Annie Elizabeth, &c. The leading varieties worked as pyramids are Scarlet Nonpareil, red and white Juneatings, Claygate Pearmain, Scarlet Pearmain, Eve Apple, Cox's Redleaf Russet, a variety distributed by Mr. William Paul, and regarded at Northampton as a very fine and useful Apple, &c.

Pears are also a leading feature. There is an abundance of handsome pyramid trees on the Quince

At the Billing Road Nurseries there are about 70 acres of trees, a general nursery stock being largely represented. In addition there are extensive seed farms, in which Potatoes, Broccoli, Mangel, Cabbage, and many other garden and agricultural seeds are grown; and there are also farm buildings and seed stores requisite for the proper harvesting and cleansing of the seeds. Large breadths of plants are also grown for covert, such as Privet, Hazel, Blackthorn, English Yew, common Laurel, Portugal Laurel, Larch, &c. All these, owing to the cool, moist summer, have made a vigorous growth. *R. D.*

Forestry.

THE general benefit of woods and plantations to a community and country are too vast to enumerate, but the following will at least illustrate some of them. Grazing is at present more profitable in this country than growing corn, and it is likely to become still more so, since, as is too frequently the case, flocks and herds die by the thousand in foreign parts for want of water, while ours at home do not suffer in this way.

FIG. 84.—WINDOW FERNERY (SEE P. 425).

stock, as well as on the Pear stock, the latter being employed principally for standards. Of the newer Pears, Beurré de l'Assomption and Souvenir du Congrès are highly thought of, and do well worked on the Pear stock. There were several pieces of two-year-old Pears and Apples in fine condition.

Plums are largely grown, especially the Diamond and Victoria, which are worked by the thousand, and sold as two-year untrained trees for market gardens or for rearing into standards.

Cherries are numerous also, worked on the common Cherry stock as well as on the French stock. Two of the newer varieties, the Early Lyons and the Olivet, the largest of the Duke tribe, are being largely worked as dwarfs. They are both very productive and of excellent flavour.

Peaches, Nectarines, and Apricots are largely grown on dwarf-trained trees, the latter especially. Some two-year-old trees had from seven to nine strong shoots each, while the one-year trained plants were very good. These are all on the Mussel stock. Peaches are also on the same stock, and of a like vigorous character. The principal varieties are Royal George, Noblesse, Early Alfred, Early Beatrice, Early Louise, Lord Palmerston, Lady Palmerston, Barrington, Bellegarde, Galande, and others. Nectarines are also well done, and include the leading varieties.

It is from cold and wet, rather than heat and dryness, that this country suffers. In the memorable dry season, 1868, when grass was very scarce, there was much more cream and butter produced than in the wet season, 1872, with superabundance of grass.

According as the breeds of animals improve for feeding purposes their constitution becomes more delicate and tender, hence arises the necessity for warming and sheltering the country to suit their new condition.

In the improvement of pasture lands it is well to consider which species of trees sweeten and improve the grass, and which embitter and impoverish it most. Where choice can be bad Oak and Larch are most injurious. In the agricultural statistics for the past year a considerable increase of permanent pasture lands is given, and a corresponding decrease in arable land, thus showing that there is a falling off in grain and an increase in grass.

On light, sandy soils much exposed the wind often in a few hours completely levels Turaiip drills, whereas, if duly sheltered by belts of plantations no such evil result will arise from it. One farm known to the writer has been given up by the tenant on account of want of shelter; and another would have also been given up but for the proprietor undertaking to plant shelter belts upon it.

The first thing to do in a waste moorland district about to be brought under cultivation is to drain the surface well, and plant shelter belts and groups with an unsparing hand, and as certain as the plantations grow up so will improvement of the land follow and keep abreast with them. Many bleak and wild districts where no one would have thought of taking up their residence even during the summer months, are now inhabited by a comfortable and well-to-do community, all the result of planting and sheltering the country.

Figures in arithmetic are excellent in their way, but the culturist who studies well the soil observes the various phenomena in Nature, and resolutely obeys her laws, will himself sooner grow rich, and thereby so far enrich his country, than he who dives deep into figures and employs much of his time in abstruse calculations.

To what extent, and in what manner trees, woods, and plantations affect the health of man, and how far they aggravate or modify diseases inherent to his constitution, is as yet unknown. Some maintain that clearing great tracks of woodland renders the climate more healthy and favourable to his constitution, while others maintain the very opposite. Now it is very

The Villa Garden.

INFORMATION WANTED.—“I wish,” remarked a Villa gardener a few days ago, “that the gardening papers would give us less information about new plants, and occasionally, in place thereof, some information how to manage old ones.” He laid no definite charge at the door of any individual paper; in fact he bore enthusiastic testimony to their great value to the horticultural community, but he thought, and probably with some substantial show of truth, that the fact that many good old things have become almost lost to cultivation is to some extent owing to the fact that they have been forgotten by the gardening Press. This fact would appear to cut both ways: things go out of cultivation because they are not referred to in the gardening journals, and having gone out of cultivation for various reasons they are unfrequently referred to by the present generation of writers.

AUTUMN TREATMENT OF POLYANTHUS.—Pointing to two lines of fine plants of Polyanthus growing on a narrow border between the line of Box edging by the side of a kitchen garden walk, and one of espalier

when this is carefully done, one good-sized clump will make from three or four to seven or eight plants. When divided, the tap-root in each case should be cut off as far as it is bare of roots, or if unnecessarily long, to within an inch or so of the lowermost leaves. These should be planted deeply, and pressed firmly into the soil. In making a bed for Primroses, or preparing spots in mixed borders for them, let the ground be dug deeply, and some manure buried to the depth of 6 inches or so. This gives a cool bottom, and something for the roots to go in search of. A top-dressing of good soil at midsummer is of great advantage to the plants.

DOUBLE DAISIES.—These very pretty and serviceable spring flowers can be treated the same way as recommended for the Primroses, as they also thrust themselves up out of the soil. In all cases Daisies do best when divided in the autumn, and if planted out in store beds in lines, after breaking the plants up into single stems, they grow into fine stuff for planting out in spring. Large clumps of Daisies, if left undivided, are pretty well certain to become impoverished and die; in this way many plants are lost by Villa gardeners.

DOUBLE ROCKETS.—At this time of the year the plants throw up fresh growths round the base of the flower-stem, and if these are removed they make good cuttings and strike freely. They are best placed singly in small pots, for if put out in the open air they are so liable to be destroyed by slugs and snails. The flower-stems also sometimes furnish cuttings, that is if the flower-spike be cut away just below the flowers; the stem will throw out young shoots, and if these are taken off and made into cuttings they strike pretty freely; but the cuttings do best when made in August. The old plants that are left in the borders to stand the winter are greatly helped by loosening the soil about them, and top-dressing with a little leaf-mould and manure.

DOUBLE PYRETHRUMS.—It is no uncommon thing to find these handsome flowers in the borders of Villa gardens; not only are they attractive in appearance, but they are also continuous in flowering, and some in our own border are yet yielding bright and attractive flowers. “What is best to be done with these at this time of the year?” is a question constantly being put. In an open and somewhat dry border or bed the plants will do well through the winter, for their great enemies are wet and slugs rather than frost. The stronger and better established plants are, the more likely are they to stand the winter; and where they are left a ring of sharp cinder ashes put round the stools at the end of October will serve to keep the slugs at bay. “But how to propagate?” it may be asked. This is a simple matter. At the end of the summer the plants throw up small side growths, and if these be carefully removed as near the stem of the parent plant, and are put singly into small pots, or a few round the sides of a large pot, they soon take root, and in this manner fine varieties can be increased. The parent plants can be divided, but this is best done at the end of March, just when the plants are getting active, and then when divided they invariably grow away safely into size.

COLCHICUM AUTUMNALE AND CROCUS SPECIOSUS.—These two plants are now extremely attractive in the open border. They have thrust their flowers up through the foliage of other plants surrounding them, and they seem to defy, in their way, the raw foggy mornings, the cold nights, and the deepening gloom of autumn. They require planting where they can remain for a few years undisturbed. The Colchicums when grown into strong crowns flower with amazing freedom, and the same remark holds good of Crocus speciosus. And there is the old Crocus nudiflorus also, flowering away with amazing ardour. We saw some large old-established clumps of this a few days ago, 18 inches to 2 feet in circumference, and they had literally “heaped up their flowers in happy plenteousness.”

Natural History.

GOLDEN BUTTERFLIES.—The year 1877 will be long remembered amongst observers of Nature for the unusual abundance of a conspicuous golden butterfly, the *Colias Edusa* (Clouded Yellow). In the south-eastern counties, especially near the coast, this butterfly is tolerably common, although in some years not one is to be seen. In other years its range is more widely extended, and instances are on record of its appearance, in particular seasons, not only in every

FIG. 85.—WINDOW FERNERY (SEE P. 425).

likely, as is often the case, that both views may be right. It has been pretty clearly demonstrated that several woody and particularly swampy districts, both in India and America, have been greatly benefited by clearing and drying, that is to say, fevers have been greatly modified or prevented by it. On the other hand, such districts as Strathspey in our own Highlands, which was formerly a dense forest, has, since the forests were cut and cleared away, become much more liable to lung diseases, such as consumption; indeed, at the present time more persons die of consumption in the Highlands than of any other diseases, or, as respects person of middle age, more than all other diseases put together. Now I am credibly informed by some of the oldest persons living that in their youthful days such diseases were little known.

How much or how little diseases, either in the human family or the lower animals, are produced by such changes as planting, or clearing, is very difficult to say; true, such and such results take place, but whether the cause and effect are these or others is uncertain. It appears to me at least that the different modes of living, especially with respect to such matters as diet, clothing, and occupation, have as much, if not more, to do with disease as any other cause or causes. C. Y. Michie, Cullen House, Cullen, N.B.

Apple and Pear trees, he asked, “What would you advise should be done with these?” They had made a robust growth during the summer, owing to the season having been so moist, and, as is customary with these plants, had thrust themselves up out of the soil. Our friend’s impression was that it would be best to lift the plants, divide, and transplant them; and this would have been the correct thing had the plants been older than they were, and not a bed of seedlings that had only partially flowered for the first time last spring. It was unnecessary to disturb them, for they were well established; and our advice was to pick away the decaying leaves from the plants, loosen the soil about them, and add a good top-dressing of soil and manure. At this time of the year Polyanthuses throw out roots close to the surface, and a top-dressing is of great value to the plants just when they are making their autumnal growth. Then next spring the best varieties should be marked, and the inferior ones got rid of.

In the case of plants of greater age that had bloomed well last spring, it would be best to divide them. We are now doing this in the case of double and single Primroses, and fancy and gold-laced Polyanthus. They are plants that had become well established, and were thrusting themselves up out of the soil. The clumps were lifted, the soil shaken from the roots, and the plants pulled asunder; for

part of England and Wales, but in some of the Scotch counties. We have not, however, had such a visit as has recently occurred for at least fifty years. The Clouded Yellow is one of those butterflies which commonly live through the winter, lying up in some sheltered place, like the genus *Vanessa*. They reappear late in the spring, and it is probable that their eggs are not deposited until that time. This year they appeared in considerable numbers about the middle of May, and as they were by no means in the same abundance in the summer of 1876, there can be little doubt that they came to us from the south-east, across the sea. They were probably accompanied by swarms of the *Cynthia Carderi* (Painted Lady), which has also been unusually abundant. The eggs of these visitors were laid in May, and the perfect insect reproduced in manifold abundance about the end of July, lasting in many places through August and September. A similar flight of *Colias Hyale* (Pale Clouded Yellow) appeared in 1842, but in far less numbers. Another well-known migratory butterfly is the *Vanessa Antiopa* (Camberwell Beauty), a flight of which appeared all over England in August, 1873. On the subject of the migration of these butterflies there is an interesting passage in Mr. Charles Darwin's *Voyage of the 'Beagle'*, chapter 8, December 6, 1833:—"One evening, when we were about ten miles from the Bay of San Blas (in South America), vast numbers of butterflies in bands or flocks of countless myriads, extended as far as the eye could range. Even with the aid of a telescope it was not possible to see a space free from butterflies. The seamen cried out 'it was snowing butterflies,' and such was in fact the appearance. More species than one were present, but the main part belonged to a kind very similar to, but not identical with the common English *Colias Edusa*. The day had been fine and calm—hence we cannot suppose that the insects were blown off the land, but we must conclude that they voluntarily took flight. The great bands of the *Colias* seem at first to afford an instance like those on record of the migrations of another butterfly, the *Vanessa Carderi* (Painted Lady), mentioned in Lyell's *Principles of Geology*, &c." C. Wolley Dod, *Eton*.

THE CUCKOO.—I can quite agree with what "Yorkshire" says in last week's issue of the *Gardeners' Chronicle* concerning magpies sucking eggs, and I think that the eggs he found destroyed were sucked by them and not by cuckoos. As an instance how easy it is to be deceived, I may mention the following incident which occurred some years ago. I saw a cuckoo busily engaged searching the shrubs and bushes, as I then thought, for the purpose of eggs, and she at last flew into an Ivy bush, where I knew a pair of wagtails' nest to be. I allowed her to remain there a few minutes. I then cautiously approached the bush, and when within a few feet of it out flew the cuckoo from the very spot where I knew the nest to be. Having the gun with me, I fired and broke the poor bird's wings, and when killing her to end her misery, to my great surprise and sorrow she dropped an egg at my feet. It at once struck me that this bird did not go to the wagtails' nest for the sake of plunder, which was fully confirmed by my finding the wagtails' eggs quite undisturbed. What she was searching for was a home for her future offspring. Another thing appears curious: how is it that the cuckoo does not suck the eggs in the nest which receives her own? for I know in some instances they are laid before those of the cuckoo. I may mention that while jays and magpies may be trapped with eggs, I never heard of any one catching the cuckoo by the same means. The nightjar is an insect-feeding bird, and what I suggest is, that the cuckoo may do in the day what the nightjar does in the twilight? In closing I hope that some of your obliging correspondents will help to remove some of the doubts that still surround the cuckoo. N. E. T., *Stammore, N. H.*

SHOOTING WILD BIRDS.—I did not read the note by "Subscriber" upon the landrail (see p. 398) with the pleasure that usually attaches to the natural history notes. The reason is obvious: your correspondent tells us of an interesting bird which he saw and then shot. Why this latter act of vandalism and useless cruelty? Why does the sportsman who carries a gun seem to regard all that is living in Nature as game for his bag, killing birds that are rare or beautiful without compunction and without sense? The schoolboy as he wends his way along the country lanes is, in spite

of the moral and religious teaching lavished upon him, so ignorant of natural history that he regards all wild birds as natural enemies, and fires away at them with stones in the hope of felling them to the earth. He is not cruel naturally, but he is grossly ignorant, and his bravery has not been diverted into a better channel. His entire ignorance is his excuse. Not so, however, is it with the sportsman: he has knowledge, and should have age and enough of discretion to guide him aright, but alas! armed with a gun and he is as thoughtlessly cruel as the schoolboy. No doubt the handling of a gun has a demoralising influence on the mind as there comes with it the anxious desire to use it upon whatever object may present itself; and if it be some rare or beautiful bird so much the better. What this poor landrail had done to make it the fitting object for a sportsman's enmity and love of destruction I am at a loss to perceive. I should be sorry indeed to boast that I had thoughtlessly or ignorantly killed any harmless bird. It is to this feeling of foolish ambition to possess these beauties of the air, that we owe our present dearth of many once plentiful wild birds. A. D.

THE LANDRAIL PERCHING.—I believe it is a very unusual thing for this bird to perch, but that he will occasionally take refuge in a tree when frightened by a dog I know; one did so last autumn when a colley dog of mine disturbed it. It flew across the road, and alighted in an Ash tree close to where I stood. The cornrake will sham death when caught, and is likewise a good ventriloquist. *Helen Watney*.

THE CUCKOO AND WAGTAIL.—For the last three years a young cuckoo has been hatched and reared by the wagtail, outside my bed-room window, in a hole in the wall. In the early part of the season I had a few pairs of pigeons given me, and accordingly I placed a box for them close by the hole, so that I might attend to them at my leisure. However, my pigeons soon left, and later on the wagtails deserted their comfortable old quarters, and built their nest in one of the compartments of the box. My curiosity being aroused, I began to wonder whether the annual young cuckoo would appear. After waiting a reasonable time (and reckoning that incubation had taken place), to satisfy my curiosity I approached the box, and discovered the cuckoo's egg with five others. I was greatly interested, and closely watched their movements. Both wagtails and cuckoo were duly hatched, and in their extreme infancy it was difficult to distinguish one from the other, the young cuckoo being but a very little the larger. It increased in size rapidly, greedily snapping up every bit of food that could be brought by its fostering parents. What became of its companions? The cuckoo soon became too powerful and saucy for them, and they were either stifled or starved to death, perhaps both. As the cuckoo became fully fledged I took it in my hand, after which it became restless, and soon left. I was sorry to see the charge of egg-sucking brought against the cuckoo, and shall be glad to learn whether either of your correspondents can prove it by ocular demonstration, without which it would be hard to accuse. If you ask any aged countryman the question, he will invariably answer in the affirmative, yet not one of them is able to speak from actual experience. Putting the question to a very old man a few days since, he replied: "Oh, yes; and that's what makes their voices so clear." It is true the cuckoo arrives with the egg-season, and departs at its close; so do caterpillars, and a host of other insects which I have been led to believe form their primary food. It seems strange to me in reference to this proceeding of the cuckoo—of dropping its eggs by chance, that she does not then and there commit the monstrous outrage of devouring the eggs of the nest in which they lay; or is she sympathetic by way of deception, for the protection of her own deposit? This seems somewhat feasible, inasmuch as the size and colour of the cuckoo's egg vary but little from that of the wagtail. Your correspondent "Yorkshire" says he is convinced that both cuckoos and magpies destroy eggs. There is no doubt about the latter, but though he is convinced that the cuckoo does also, he has failed to particularise it. It is not uncommon for the wagtail to build its nest in shrubs, especially when growing against walls. A few years since, at Cricket Gardens, the seat of Viscount Bridport, a wagtail made her nest on the surface-soil of a fine Heath specimen that stood inside the door of one of the conservatories. The little creature was careful to raise the edge of her

nest to the height of the pot-rim, seemingly to allow for the man watering. The conservatory was usually closed by night, and one morning an egg was found on the door-mat: this was of course carefully placed in the nest, and afterwards the sash was left a little open for egress and ingress. The wagtails were hatched and reared quite unconcernedly, much to the amusement of every one who saw them. So much for the domestic instinct of this little favourite. *F. Mullins, Beaminster, Sept. 24.*

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—The ripening process in all deciduous, or partially deciduous, stove plants, of which Allamandas, the twining *Clerodendrons*, *Bougainvilleas*, and *Dipladenias*, may be taken as the leading representatives, and which was advised to be commenced a short time ago by withholding water, all the light available, and the admission of more air, must be continued for some weeks yet. The most useful character of these plants for early flowering, with their ability to afford a succession through the summer and autumn, is sufficient to establish them amongst the most desirable subjects that can be grown, totally apart from their use as trained specimens, where needed for exhibition purposes. But in the treatment of these and all similar plants for producing their flowers freely early in spring, say from the beginning of April to the middle of May, it is necessary to do much more by way of a thorough ripening of the wood at this time of the year than by many is deemed requisite, and without this it is useless to expect them to bloom early and freely. It is no uncommon occurrence to see plants of the above cut back and started in a brisk heat by the end of the year, or soon after, when they push growth, but make weak puny shoots that refuse to produce flowers in anything like quantity until mid-summer or later. The cause for this is often erroneously assigned to the application of too much heat early, but which generally might be much more correctly attributed to the soft, immature condition of the wood, resulting from the indifferent usage they have received. It would just be as unreasonable to expect a good crop of fruit from badly-ripened Vines or other fruit-bearing trees when insufficiently ripened, as it is to look for flowers from hard-wooded plants of the above nature that have to be cut back each year, when not properly prepared. I am led to these remarks by a knowledge that at the present time, in almost every garden, large or small flowers for the decoration of stands, vases, or similar contrivances are continually in demand, and through proof based upon the use of these plants for many years, that where a stove is at command there is nothing that can be grown that will give such an abundance and lengthened supply as the above subjects, when the ripening process has been effectually carried out through the autumn previous. Where a sufficient number are grown a plant or two of *Allamanda* and *Dipladenia* may be kept on flowering up to the end of the year by giving them a position at the warmest end of the stove, but as a matter of course there must be no stint in the supply of water, as advised for the earliest ripened plants that have to be started the first. *Gardenias*: The earliest of these—whether grown on from cuttings or cut back after flowering—that have now got their flower-buds a good size, should have a brisk heat to induce them to open freely. The supply of water must also be so regulated as to be sufficient but not in excess, as if the roots are allowed to get too dry, or the opposite, very wet, the buds have a tendency to fall off much more at this time, when growth is languid, than in the spring. *Gardenias* through the dull season of the year are also very liable to throw off their buds when the plants are placed under conditions of insufficient light, often caused by plunging them in bottom-heat at a considerable distance from the glass; but if instead of this they are raised up on inverted pots or temporary shelves so as to be near enough to the light much more satisfactory results will follow. *Bouvardias* that have been in frames and pits with just sufficient warmth to keep them moving must now be put where they can receive more heat. It is well to divide the plants so as to bring them on in batches at intervals. To bloom them freely through the winter they should not be subjected to a lower temperature than 65° in the night. There are few places where these most useful and continuous flowering subjects might not with advantage be grown; a shelf on the back of a Picea stove, or a row of plants stood on the curb of the plunging pit take up little room, do no injury to the permanent occupants, and in such a position will furnish a supply of cut blooms all through the winter. Form, colour, scent, and enduring capabilities alike

place Bouvardias amongst the very best flower-producing plants we possess. Their medium-sized compact habit, with ability to go on making fresh growth and bearing flowers on every bit of young wood they form renders them suitable for growing by those who have little room for stove subjects in general, and were they but better known there is no doubt their culture would be much extended. Another advantage is, they do not exist in such unlimited numbers as to make a selection perplexing; *B. Hogarth*, scarlet; *B. Humboldtii* corymbiflora, white; *B. jasminoides*, white; and *B. Vreelandii*, also white, a remarkably free bloomer, and compact in habit, will be found second to none, and these varieties will be sufficient for the requirements of most growers. Autumn flowering *Salvias* that have occupied cold pits or been stood out in the open air during the summer should have a little warmth given them through the autumn; they too ought to have all the light that can be afforded them, not crowding the plants too closely together. A limited number, grown with sufficient room and favourable conditions generally, will produce many more flowers and keep on blooming longer, than when too many are attempted to be grown for the space that can be devoted to them. It will be well now for some weeks to redouble the exertions made in the destruction of the worst species of insects, such as mealy-bug and scale, so difficult to deal with on evergreen stove plants. As I have frequently urged, it is impossible to grow stove plants satisfactorily where mealy-bug exists; the plants whilst small may be dealt with in a way that will keep the insects in check, yet in their case at an expenditure of labour greater than all their other cultural requirements put together; but as the specimens attain a size such as enables the production of flowers in the quantities necessary to exemplify their useful character, the work involved in keeping the bugs under becomes intolerable. Its total eradication, no matter how numerous, is not impossible, and it would be difficult to point to a wiser economy than following up its destruction so as to lead to complete extermination. At no time of the year can this be so effectually done as the present, when the whole season's growth has become sufficiently matured to bear without injury stronger applications than in summer, of whatever insecticide is employed; but whichever is used nothing less than complete and repeated immersion of the heads of the plants, or a repetition of syringing so thoroughly carried out as to reach every crack and crevice in the bark, leaves, and foot-stalks, will suffice. *T. Baines*.

ORCHIDS.—The growing season being now well advanced, and a considerably less amount of light at command, it will be incumbent on those who have the charge of these plants to use such means and adopt such treatment as shall induce and assist the thorough ripening of the growths and bulbs already formed, and at the same time the speedy completion of those that as yet are only in a half-finished condition. For a week or two the shading required will be reduced to the barest amount possible; in fact only where any structures are so built as to get the full force of the sun at mid-day will any be required at all, and then only for about a couple of hours, say from 11 A.M. to 1 P.M., it being better just to shade for a short time, for by withholding it altogether the risk is often run of many of the plants in baskets, through being so near the glass, having their leaves burnt, and consequently being disfigured for a long time to come. In houses thus situated it will be necessary to bear this in mind, and in these and all others the object must be by well regulated exposure to light, air when the weather is favourable, and less water at the roots, to harden all the growths as they are formed, so that when dull and dreary winter is upon us the plants may remain healthy, though in many cases they will appear to be inactive. The night temperatures should now be—East India-house, 65°; *Dendrobium*-house, 60°; *Cattleya*-house, 58°; *Odontoglossum*-house, 55°. The lowering of the night temperatures will materially assist in the hardening of the tissue, and also one of the chief means of retaining the leaves on the plants of such as are evergreen, it being certain beyond a doubt that the cause of many, East India plants more particularly, losing so many of their leaves being the high night temperatures to which many are subjected, coupled with the fact that they are during the winter months treated far too liberally to heavy supplies of water.

The Pleione now will need careful treatment. As the leaves turn yellow and fall off it will be necessary for a few weeks to lessen the amount of water, only giving just enough to keep the soil moist and the bulbs plump. The flowers will very soon be showing themselves, first on *Wallichii*, then *lagenaria* and *maculata*, and later on during the winter the distinct *humilis*. Whilst the blooms are on the plants it will not do to give much water, otherwise the flowers soon lose the freshness of their colour, and quickly damp off; but as soon as the flowers are off, and the young leaves appear, the treatment given must be that accorded to a growing plant. These are all easily increased, most of the large bulbs breaking

double, and in some cases three young shoots appear. *P. humilis*, however, will often send out one or more small breaks around the bulb, beside the leading growths; and during the summer the old bulbs, which do not shrivel and dry away so rapidly as in the other species, will send out a dense tuft of small leaves from the top of the bulb in the axils of the old leaves, which ultimately form small bulbs. These should remain till the early spring, and then be taken off and pricked out carefully in a small pot, placing them near the edge of the pot. Though *Oncidium Cavendishianum* cannot boast that it is of recent introduction, and therefore be recommended on the plea of novelty, it is, nevertheless, of such a showy and useful nature that an allusion to it here may not be out of place. Anything of real worth that flowers during the winter is doubly valuable; and in this, with its long branching spikes of flowers, the labellum of which is of a cheerful yellow colour, we have one that is very acceptable and desirable, and should be in every collection. *O. bicallosum* is in many respects similar to this; the leaves of *bicallosum*, however, are rounder, flatter, and less pointed than those of the former, whilst the spike of *Cavendishii* appears directly the growths are formed; the same occurrence, however, does not take place in *bicallosum* until two or three months have elapsed after the finishing of the growth. The spike, too, of *bicallosum* is much shorter, the number of blooms considerably less, but these are of a larger size than those of *Cavendishianum*. They are best grown in pots, placed well up above the rim, and stood in the *Cattleya*-house, and enjoy a good share of light at all times. The leaves, being very thick and fleshy, are capable of standing firm and green with but a small quantity of water during the resting season. *W. Swan, Fallowfield*.

FLOWER GARDEN, ETC.

The time is now at hand when extra attention is required to keep everything as clean and orderly as circumstances will allow, and as the leaves have begun to fall the lawn near the family residence should be swept every morning. Frost sharp enough to mar the beauty of the flower garden may be expected any day. Have potting material and pots in readiness that whenever the plants show that the cold weather has taken hold of them all the tenderest and most desirable should be lifted and stored away for the winter. We always begin with the tricolor and variegated *Pelargoniums*, then any of the other sorts of which the stock may be limited. In some gardens it is occasionally wished to have the flower-beds left entire as long as possible, but it is rather a risk, and is better if it can be avoided, for the best plants may get so injured that a large percentage of them may be entirely lost, and the others rendered unsightly for the winter. This entails a great deal of anxiety and extra labour in spring, when the stock must be made up to the required number. Where the turf has become unlevel it may now be lifted and relaid, using sand or any light soil to make up the ground. By having all such work done early the grass gets rooted before the cold weather sets in, and labour is economised at a busier season of the year. Where the ground is sufficiently moist, or in dry localities after the first rain, shrubs and trees may be transplanted. By having this work done early, while the temperature of the ground is considerably higher than after the autumn rains, the plants get established and form fresh roots before winter. Give water according to the state of the ground and the requirements of the plants; but much water is seldom wanted at this time, and is often injurious. There are so many ornamental trees and shrubs with beautiful foliage that most pleasure-grounds may be greatly improved with an addition of those interesting plants, which can be had at a moderate price in all the best nurseries. Fruit-bearing trees may also be used with good effect. Annuals, such as *Nemophila*, *Collinsia*, *Godetia*, *Saponaria calabrica*, *Mignonette*, &c., may be sown in beds and flower borders for a display in spring and early summer. Take the first opportunity after rain to have the walks rolled down smooth that may have been broken up. *T. Blair, Shrubland Park*.

HARDY FRUIT GARDEN.

The change of the leaf with a sting of frost in the air are unmistakable tokens that winter is fast approaching and that it is high time to prepare for its advent, as the season will soon be here when planting operations should be commenced in good earnest. There is nothing like beginning this work early, as then the trees at once set about repairing the injury caused by removal, in which they are greatly aided by the heat in the ground now slowly and gradually effecting its escape. There is an idea prevalent that the roots of deciduous plants are dormant throughout the winter, but that is a most erroneous notion, as may readily be proved by any one who will take the trouble to examine them a month or so after a tree or shrub has been transplanted or laid in, when they will find them bristling with white, fresh formed fibres. This I

have seen repeatedly, but the thing is so patent by what may be observed above-ground in the gradual swelling of the buds with their slow and steady development after the fall of the leaf that one feels as sure of what is taking place below, as if open to the vision, and that the feeders, although not so active, are ever at work building up and forming fresh organisms. If arrested in this work after the turn of the year they have not time to recover the check, and the result is that the buds break feebly, whereas if planted early they push out strong and vigorous, and make double the progress during the summer they otherwise would. The advantage, therefore, of getting all fruit trees in as soon as the leaves are fairly off will at once be seen even by the most inexperienced; and that all may be ready when that time arrives, soil should now be got in, and stacked up near where it will be required for use, so as to save labour in wheeling, and to have it in suitable condition for chopping up if the weather during November happens to be wet and unfavourable.

Trenching as a preparatory measure for the planting of all kinds of bush fruit should likewise be taken in hand, for to grow any of these well the ground must be stirred deeply, that the roots may ramify freely and be out of reach of drought during the heat of summer. In all well managed gardens, plantations of such things as Gooseberries, Currants, and Raspberries are never allowed to stand to attain old age or become unsightly objects, as the positions or quarters they occupy can always be turned to good account after such a rest where a regular and systematic mode of cropping is carried out. It is the practice with some to plant Gooseberries and Currants near walks, so as to form narrow borders on which to grow Strawberries or other low-growing crops, and the plan is a good one, inasmuch as it is a saving of ground, and the arrangement gives an air of order and neatness, as well as improves the quality of the fruit by being so fully exposed to the influence of sun and air. The Raspberry, however, being more of a surface-rooting plant and fond of partial shade, with a cool loose soil to grow in, does best in plantations by itself, as there the ground can be mulched over and left undisturbed, as it should be, except any hoeing that may be necessary to extirpate weeds. The best crops and the finest fruit I ever saw were grown on canes that stood near a building, by which they received shelter from the sun for a few hours during the heat of the day; and in choosing sites for planting such positions should be taken advantage of, especially where land is of that light dry nature as to be unsuited for their culture. Autumn-bearing kinds require more exposure to ripen the fruit and give it its proper flavour, but the situation for these should be so chosen as to be out of reach of strong winds, or they get sadly knocked about and so damaged as to be of little value. In trenching and preparing the ground for planting Raspberries plenty of short decomposed manure should be worked in if the soil is light; but if of an opposite character, leaf-mould or decayed vegetable rubbish of any kind will be more suitable, as either of these will assist in keeping it open, and any stimulant will be better applied as a top-dressing during the summer. The ingathering and storing of Apples and Pears must now be proceeded with, as we have already had slight frosts, and although not yet sufficient to injure either as regards keeping, they are likely to suffer in flavour if left much longer exposed. In plucking them from the trees it is best to make two classes, so as to avoid further handling or loss of time afterwards in looking them over to separate the sound from the unsound, the latter of which will come in for present use. *J. Sheppard*.

FRUIT HOUSES.

MELONS.—The magnificent weather which has prevailed since the middle of September having been all that can be desired, late Melons are swelling fast, and the quality, where summer-heat has been maintained, is excellent. Water must henceforth be given more sparingly to plants in all stages, particularly to those which are carrying fully-developed fruit; but a thorough soaking should be given to the latest plants on fine mornings when watering is absolutely necessary, and if at hand some dry mulching may be spread over the tops of the pots to prevent evaporation. Keep the foliage thin and evenly placed, so as to admit every ray of sunshine and a free circulation of dry, warm air when fire-heat is necessary. As days decrease in length the superiority of fruit from pots placed immediately over the bottom-heat pipes will more than compensate for the trouble saved by growing them in large masses of cold sour soil, as Melons of indifferent flavour are worse than useless, and it is better to leave off with a good fruit in September than to prolong the season with Melons which ripen after the leaves have passed away. Plants in pits and frames must be kept as dry and warm as possible by frequent attention to the linings, and by judicious thinning of the foliage and elevation of the fruit. Let the glass be well washed inside and out, and mat well at night. *W. Colman*.

THE
Gardeners' Chronicle.

SATURDAY, OCTOBER 6, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, Oct. 8—Sale of Dutch Bulbs at Stevens' Rooms.
TUESDAY, Oct. 9—Sale of Specimen Azaleas and Orchids at Stevens' Rooms.
WEDNESDAY, Oct. 10—Sale of Dutch Bulbs at Stevens' Rooms.
SATURDAY, Oct. 13

THE growers of the POTATO have held their annual gathering; and although, unlike the average run of autumn assemblages, there has been little talk, there has been no lack of display, and that of useful works and remarkable results.

In looking over the singularly fine collections that covered the tables at the Royal Aquarium on Wednesday, the first question that presented itself to the mind of the practical inquirer was—Under what conditions of soil and culture are these marvellous samples produced? Is it by ordinary culture such as is adopted by nine-tenths of those who cultivate Potatos, or is it by some magic means known only to those favoured few who constitute the chief prize-takers at the show? Probably the most successful of these would be the first to discountenance the notion of anything magical about the proceeding. The lessons derived from many years of successive cultivation have not been lost upon them, and if perchance some are favoured naturally with soil that would produce handsome Potatos under any conditions, yet there has been no lack of care displayed in the selection of seed tubers, of efficient stoving, and in the general cultivation of all of which success has been made doubly certain. Yet in one case a successful competitor in several classes was enabled to say that his success was entirely due to ordinary field culture, in soil of moderate quality, but where the production of good clean seed samples was of the first consequence, and from these had been selected his prize tubers. That such should be the case is strong evidence that the opinions we gave expression to last week as to the superior quality and value of medium-sized tubers over large ones have not been without effect, and this knowledge should spur others to enter the lists as competitors, as the fact thus mentioned entirely explodes the notion that only by some magical mode of culture can show samples of the Potato be produced.

Perhaps the most striking feature apparent in the general collection of tubers was the excellent average quality present, and the comparative absence of coarse, large, ungainly tubers. A few growers of the old school, but new to the International Potato Show, brought some of their cattle-food kinds, but these only served by comparison to show how far ahead the perfect exhibition tuber was of such samples as these. The judges of the Potato show will have done a good work if by their awards, consistently made from year to year, they can eliminate the most undesirable quality of mere size from the Potato to a great extent, and perhaps eventually altogether. To attempt to ally art with a show of Potatos will doubtless appear to some cynical minds as the height of absurdity, and yet can any unbiassed visitor to this exhibition of tubers deny that its teachings were not largely of an æsthetic kind? A Potato is but a Potato after all, but there is found in many, shall we not say in the larger portion, of those staged on Wednesday beauty of form, curves perfect in outline, bodies of elegant proportions, variety that is ever charming in colours and markings, and, not least, that clearness of skin and polish which betokens refinement; and do not all these features

educate the eye and fascinate the imagination? The uncultivated visitor in taking a cursory look over the show alights upon the prize collection from among many others. He asks at once "Why does this lot stand before its neighbour, for in the latter there is more material for the pot, and that is my only notion of a Potato?" But in the prize lot a closer inspection reveals more refinement, more beauty, more evenness; the form of each tuber is almost perfection, and thus he is taught to perceive that art in a humble way has entered into the judgment, and in the award has found expression.

One phrase was frequently heard in the show after the awards were made—"The judges have gone in for quality"—a phrase well understood as indicative of beauty in preference to ugliness, and form and evenness in preference to size. To this version we, however, beg to add the wider and, perhaps, more suitable one—viz., that which we so strongly urged last week: medium size, or the greater proportion of nutriment in the tuber as compared with the greater proportion of water in large ones. Therefore quality in its widest Potato sense means not only beauty and other external virtues, but also the essential one of superiority as an article of diet—the most valuable feature to be found in any Potato. Perhaps, also, the judgments generally tended to explode the idea elsewhere suggested that a tuber of 10 ounces in weight was a fair average size for exhibition purposes. It cannot be too strongly urged that the Potatos of the show-table and those of the dinner-table ought to have, in regard to size, very considerable affinity. Unlike plants and flowers, which are grown only for the delights they render to the eye and nostrils, the Potato is essential as an esculent, and if it were not this it would never have found its place in gardens or on exhibition tables.

The first consideration in all cases with judges should be, How far are the samples before us suited for the dinner-table? Of course we do not refer to the diverse qualities that may be found in various sorts, because these differ materially with soil and situation, and can hardly be included in the calculation; but if we take the size that finds most favour with the consumers we find that tubers ranging from 5 oz. to 6 oz. each are the favourite bulk for that purpose, and that size should prove the safest guide with those judges who desire to have the size of the exhibition tuber and the edible tuber in close alliance. Perhaps the most perfect dish of tubers in the whole show was the dish of Rector of Woodstock, to which the 1st prize was awarded in its class for a single dish of white round kinds; these tubers averaged three to the pound, and in size and all other essentials were the acme of perfection for table consumption.

A fitting question was asked in the show—"With all these fine samples before us, we know nothing as to their productiveness?" That feature could, of course, only be known to the grower, but it is a question that ought to be replied to, and that satisfactorily. It is a very safe platitude to assert that two blades of grass are better than one, because it is a self-evident truism. To assert, however, that size is indicative of a heavy crop is scarcely so apparent, inasmuch as with the Potato generally the greater size usually indicates the more disease; farther, size alone goes for nothing when the plants produce two big ones instead of six smaller ones; and, farther still, if, as we repeatedly urge, size indicates not bulk of food, but bulk of water, then size in all respects is the reverse of advantageous, and is to be highly deprecated. The extra blade of grass desired in the Potato is rather that the plant should produce two pounds of tubers more in quantity, not in size, than a similar plant before produced. On this head, however, all the growers were silent, not because they so desired to be, but simply

because the organisation of the arrangements of the show are so crude that nothing is done, beyond showing the tubers, to let the public understand how these tubers are produced, and what are the varying features of the respective kinds. May we not urge that something should be done in the future to remove the apparent taciturnity which at present seems to overshadow the doings of our Potato friends?

Here we had a gathering in our midst of all the most famous exhibition cultivators of this delicious vegetable in the kingdom; they had come from all parts of the country to pay homage to their favourite tuber. What a wealth of experience these men must possess of the cultivation of the Potato in their varied climes, soils, and situations; they are all, more or less, suffering from the attacks of that fell disease that year after year plays havoc with their crops, and in face of it are powerless for good. It is not a personal or local danger, it is a national one, and, we might almost say, an universal one. Here, then, are reasons broadly and clearly stated why the promoters of the International Potato Exhibition should in future years endeavour to turn their gatherings to some practical account. These exhibitions have all proved to be complete successes, not in all cases perhaps pecuniarily, but with that matter we have at present nothing to do. So far as they have brought together remarkable representative collections of Potatos, that year by year grow in beauty and quality, so far have their efforts met with complete success.

It now only remains for them to develop in the future the wide knowledge and experience the cultivation of these tubers have brought into play. They must take a leaf out of the book of the modern congress, and utilise the idea to some good purpose. There may be much talk and perhaps some nonsense spoken, but this will creep out in the best regulated assemblies. The grain can be winnowed from the chaff, and perchance it may again grow and produce further knowledge, till at length the problem of the Potato disease and its eradication may be solved for all time.

— THE Rev. W. C. RAFFLES FLINT, M.A., Vicar of Sunningdale, has presented to the Zoological Society a BUST of his uncle, Sir STAMFORD RAFFLES, F.R.S., the Society's first President. The bust has been ably executed by Mr. RUDDOCK, West Street, Pimlico, after the original by CHANTRY, and it has lately been placed in the new lion-house in the Society's gardens, Regent's Park. Sir STAMFORD RAFFLES devoted himself to active researches in natural history during the whole period of his residence in the East, where, as Lieutenant-Governor of Java, and then of Sumatra, he had great facilities for making fresh acquisitions both of the flora and fauna of the Eastern Archipelago. The largest known flower bears his name, *Rafflesia Arnoldi*, a life-size model of the flower and flower-buds of which may be seen in the Kew Museum, No. 3. His discoveries in zoology were published in the *Transactions of the Linnean Society* in 1820, but the fruits of his subsequent labours in the various branches of natural history were lost to the world in the total destruction by fire of the ship *Fame*, in which he was returning, with his family, and the results of his years of labour, in 1824. On reaching England he expressed his opinion of the possibility of establishing a society somewhat upon the plan of the *Jardin des Plantes* at Paris, and enlisted in his cause Sir HUMPHRY DAVY. His hopes were crowned with the utmost success in the following year—1825—when the Zoological Society of London was established. To it he bequeathed the remains of his valuable collections; but he scarcely witnessed in reality more than its splendid commencement, and died in 1826 at the early age of forty-five.

— Mr. D. SYM SCOTT, forester, Ballinacourte, writing to the *Journal of Forestry* on the subject of PRESERVING FENCE POSTS, remarks that "the proper

FIG. 86.—STUARTIA VIRGINICA, NAT. SIZE; FLOWERS CREAMY WHITE.

seasoning of timber before being used in any sort of structure is far more important than the season of the year it is felled in, kind of timber used, or preventatives employed. There are paints, washes, and heterogeneous steeps recommended for preserving posts, but each is comparatively costly, and only partially successful. One great objection to the application of solutions externally rests on the fact that the sap, being confined, accelerates decomposition in the interior. Most foresters must have observed this. What I would recommend with fencing posts is, the materials, when felled, to be directly sawn into posts and stored under sheds thoroughly ventilated, where they will remain at least a year exposed to 'sun and wind.' The neck, or part between wind and water of each post should be slowly charred over a strong fire—slowly, because our principle means heating the timber thoroughly to the heart, so as to extract any moisture which may be still lodged at the centre, and hardening a crust on the surface of the posts. Afterwards, to prevent the posts absorbing water, they should be well coated with coal-tar, having its acid destroyed with fresh quicklime. The tar should be thoroughly boiled to evaporate all watery matter, and applied boiling hot. A large tank holding the posts set on end, and filled with the scalding tar from a boiler answers the purpose very well. Of course the upper half of the posts can be painted when placed *in situ*. I am fully convinced coal tar, properly applied to thoroughly seasoned timber, is far more effectual in preserving posts than creosoting, poisoning, kyanising, or all the paraphernalia of iron prongs, sheet iron wrappers (an American invention), &c. One great recommendation in favour of the above process is that it requires no skilled labour, and the cost is a mere trifle."

— The death of Mr. CHARLES STUART, at Woodstock, New South Wales, is announced. For the last thirty years Mr. STUART has been known as a collector of Tasmanian and Australian plants.

— Mr. RICHARD SMITH, of Worcester, has favoured us with a sample of his beautifully-coloured and excellently flavoured new WORCESTER PEARMAIN APPLE, which has before been recommended to planters in these columns, on account of its extremely showy appearance and other good qualities. Mr. SMITH states that it crops as freely as Lord Suffield, and its season is from August to October.

— In order to show how scarce some of the fine old named GOLD-LACED POLYANTHUSES of a quarter of a century ago have become, the sum of 6s. each was asked for by and paid to a Middleton (Manchester) florist for plants of Maud's Beauty of England and Hulston's Earl of Lincoln, so difficult is it to obtain plants of these varieties. In the edition of THOMAS HOGG's *Treatise on the Auricula, Polyanthus, &c.*, published in 1822, the author gives a list of forty-two named varieties of Polyanthus, and of these only three in all probability could be found, namely, Cox's Regent, Pearson's Alexander, and Steed's Telegraph. The second of these is a fine variety, but exceedingly scarce. The most common of the named varieties are Cheshire Favourite, Exile, Lancer, and President (Hilton). Two grand old flowers, viz., Kingfisher (Addis) and Lord John Russell (Clegg) are, it is feared, quite lost to cultivation. That the named Polyanthus of the gold-laced section are rising in favour is seen in the fact that any cultivator known to have a plant or two is deluged with applications for offsets, and in all probability some of the varieties have succumbed to excessive propagation. With this great scarcity of named Polyanthus it is amusing to find seed lists containing offers of gold-laced Polyanthus seed "from the finest named varieties," and we are tempted to ask "Where do the named varieties of gold-laced Polyanthus exist from which seed appears to be so plentifully obtained?"

— There is now appearing, sheet by sheet, a supplement to the *Botanische Zeitung*, entitled *Die Schutzmittel der Pflanzen gegen Thiere und Wetter-ungunst und die Frage vom salzfreien Urmeer*, or, in English, "Preservatives of Plants against Animals and Unfavourable Weather, and the Question of a Primeval Fresh-water Sea," by OTTO KUNTZE. This work is a kind of preliminary essay on the development of plants and animals, and the struggle for existence between the members of the two kingdoms, with

special reference to the means of protection plants possess against eradication by animals and unfavourable climatal conditions. It is an amplification of three lectures given on the same subject, and embodies the author's observations during a voyage around the world. Regarding this as a distinct branch of botany, the author proposes calling it "phytophylakteriology"—a word that is sufficiently expressive, but abominably ugly and inconveniently long. He also discusses the probability of the sea having originally consisted of fresh water. When completed we may have occasion to refer to this publication again.

— Messrs. CARTER & Co. have forwarded us a specimen of the finest GREEN-EYED monster of a DAHLIA we have yet seen. The flowers proper are not produced, but the scales of the receptacle, instead of being relatively inconspicuous, are here very numerous and bright green. We do not suppose the florists will give it a certificate, but the lover of curiosities and the botanist will appreciate it. It is not new, but it is the best specimen of the kind we have seen.

— One of the fine NEW AURICULAS raised by Mr. JOHN READ, of Market Raisin, named Dr. Horner, is now in course of distribution by Mr. JONATHAN BOOTH, Failsworth, Manchester. It is a fine grey-edged variety, a well proportioned flower of good size, and was much admired at the last exhibition of the National Auricula Society at Manchester.

— The seventeenth annual exhibition of the BIRMINGHAM AND MIDLAND COUNTIES CHRYSANTHEMUM SOCIETY is to take place in the Town Hall on November 21 and 22. In addition to prizes for plants in pots and fruit, some special prizes are offered; one of them, given by a tradesman of the town, is a bottle of scent "for the best arrangement of flowers for the hair." This, if it does not bring a considerable competition from the fair sex, will no doubt prove of great interest for them; but who shall be considered competent to award the prize? Surely a living form, if not a lay figure, will be necessary, in order to display the arrangements to the best possible advantage. Madame TUSSAUD might be invoked to send down a detachment of female figures from her exhibition, to give a completeness to the competition.

— Among the more interesting subjects recently brought forward at the meetings of the Berlin Horticultural Society was a *TROPEOLUM* flower in which the entire plan of construction was reversed. In the place of the normally odd posterior sepal were two spurred sepals, and the odd one was anterior. Further, only two, instead of three of the petals were bearded. The stamens also, which were otherwise like the normal ones, discharged their pollen in a contrary order; and the carpels were also reversed in position, two being posterior, and the odd one anterior. Another flower with two posterior spurs had four beardless petals, and a third one was observed with nine stamens. A *Fuchsia* was exhibited in which the parts were in threes, and a second flower was developed on the upper side of one of its sepals. Dr. ASCHERSON described a hybrid *Dianthus*, between *D. superbus* and *D. barbatus*, and enumerated upwards of a dozen different crosses between various species which have been found in central Europe. Dr. WITTMACK showed specimens of *Peronospora sparsa*, Berkeley, which until last year had not been observed in Germany. It appeared in a Rose forcing-house in the vicinity of Berlin, and eventually overran the whole of the plants so that they perished.

— It is stated in the *Berliner Monatschrift* that *CRATÆGUS PYRACANTHA* is hardy, whereas *C. crenata*, a Himalayan form, usually regarded as a variety of *C. Pyracantha*, is tender. In the same number Dr. TSCHAPLOWITZ commences a series of articles on water and warmth in their relations to plants, and with especial reference to their management and application to plants growing under glass.

— One of the best of late flowering summer plants is the old *GAZANIA SPLENDENS*, which is rarely ever so attractive as during the months of September. During the bright hot weather of summer the flowers close directly the sun's rays are withdrawn from them, but in autumn the blooms remain expanded during the hottest weather. It is

very free of bloom also, and as successional plants are as valuable in the flower garden as anywhere else, the *Gazania* deserves employment for the purpose. In the garden of Mr. GEORGE DUNN, surgeon, Stevenage, the *Gazania* can be seen taking on a semi-double form; that is, from the centre of the flowers have issued a number of quill-like florets, which fill up nearly the whole of the centre of the flower. This may not be an uncommon occurrence, but if the sport were followed up, a perfectly double flower, like a *Ranunculus Marigold* might be obtained in course of time. The double *Pyrethrums* originated in much the same way.

— The usual monthly meeting of the HORTICULTURAL CLUB was held on Tuesday last, when the following new members were elected:—Dr. Newington, Ticehurst; Messrs. E. G. Smeaton, Waltham Green; T. Serle Jerrold, Avenue Road, Shepherd's Bush; and J. C. Fowler, Cumberland Lodge, Lewisham.

— There is in the Billiog Road Nurseries of Messrs. JOHN PERKINS & SONS, Northampton, such a clump of the DOUBLE FURZE as one seldom meets with. It is 22 yards in length by 5½ yards in width, and is of a very dense growth. It is grown for obtaining cuttings from, the double Furze being in great demand for covert. During the month of May, when this really grand bank of Furze is in full bloom, the effect is very fine.

— Introductory lectures at medical schools are, as a rule, apt to be perfunctory performances, abounding in vague platitudes and good advice, strongly tinged with dreariness. We had the opportunity of bearing one the other day, however, of such a character as to justify our alluding to it in this place. The lecturer was Professor LISTER, of King's College, the gentleman appointed to succeed the late Sir WILLIAM FERGUSSON. Never was a greater contrast observable between both the method and the matter of these two eminent surgeons than was that of which the theatre of King's College was the scene on Monday last. The subject of the lecture was one in which plant-growers are as much concerned as surgeons, and hence the propriety of our reference to the matter. Fermentation and putrefaction, as affected by the introduction and propagation of fungoid germs, or of other bodies capable of exciting fermentation and decay, formed the theme of Professor LISTER's address. His experiments, the results of which were shown to the audience, showed conclusively that, provided fungoid germs, bacteria, or other ferment-generating bodies be carefully excluded, blood neither coagulates nor putrefies, milk remains sweet, and so forth. The bearing of all this on the generation and spread of various fevers, diphtheria, and on the healing of wounds is obvious, and its relationship to the spread of the Potato murrain, the oidium of the Vine, and other plant diseases, is not less apparent.

— Mr. MUSSELL, late gardener to the Right Hon. Sir W. HUTT, Bart., at Apley Towers, Ryde, has been appointed gardener to E. A. DRUMMOND, Esq., at Cadland, Southampton. Those who have been in the habit of visiting the gardens at Apley Towers during the last eleven or twelve years can well judge of Mr. MUSSELL's abilities as a gardener. We also hear that Mr. HARDING, gardener to the Rev. W. ARTHUR, Clapham Common, is appointed to succeed Mr. COLLIE as gardener to the Marchioness of HUNTLEY, at Orton Hall, Peterborough.

— For conservatory decoration the new hybrid *FUCHSIA*, EARL OF BEACONSFIELD, is worthy of high commendation, as the flowers are large, bold, and striking, and numerous produced. In point of form it would scarcely pass muster with the strict florist, but its vigorous habit, free-flowering character, attractive appearance, and somewhat distinct character, will cause it to be sought after for embellishing a greenhouse. A Continental variety, named Madame Jules Mensrean, very nearly resembles it in character, but the Chiswick trial this summer proves it to be distinct from Earl of Beaconsfield.

— Some of the PRIMULACEÆ appear to be very active this autumn. The single and double Primroses, show and alpine Auriculas, and Polyanthus are all flowering much more than usual. Generally show

Auriculas are seeding up autumn trusses, but though they are pleasant to look upon they never attain to that perfection which is presented in the spring. It sometimes happens that certain varieties will form a truss, but keep it low down in the heart during the winter, and when this happens it comes up slowly in spring and invariably unfolds glorious pips. Some of the varieties having powdered foliage take on a charming winter dress during the winter. A variety of *Primula Auricula* known as *marginata* has during the winter mealed foliage of an exceedingly attractive character, more so, perhaps, than any *Auricula* in cultivation. The young leaves put up at this time of year are white with the peculiarly beautiful farina with which they become clothed at mid-winter. It is only those who cultivate this "beautiful and fascinating flower" that can come to understand something of the constant changes in its leaf garb which it is continually presenting. It is always active in a more or less degree, and there is scarcely another class of plants that presents such a variety in the character of the foliage as the *Auricula*.

— We intend shortly to publish a coloured plate, by Mr. WORTHINGTON SMITH, representing a group of EDIBLE MUSHROOMS and OF POISONOUS FUNGI which might be mistaken for them.

— Mr. D. T. FISH requests us to state that he has resigned the editorship of the *Villa Gardener*.

— Look out, gardeners, and all you that have plants to grow which will get dirty, and which will become a prey to aphids and thrips, red-spiders (and green ones!), mealy-bug, and scale, notwithstanding all your exertions to the contrary. Long have your tempers been sorely tried by these most destructive and ubiquitous pests, which will persist in multiplying and thriving in spite of all the wonderful antidotes that have so persistently been placed before you. Take courage, we say, your millenium is at hand! Your troubles are to be reduced, and your hours of labour considerably curtailed. In winter and spring your only anxiety will be about the frost; in summer, as far as insects and cleaning plants is concerned, your leisure will be abundant, so that there will be no excuse now for your not rubbing off the rust that will grow upon those who cannot find time to take an occasional peep over their neighbours' fences. At last the good time has come that you have so long been looking forward to—at least, if we may credit a circular that has reached us relating to a certain chemical manure, and some extracts from which we append, with the hope that you will not be disappointed by a perusal of them.

"Bouvardias, Roses, Pelargoniums, Cinerarias, &c., which are so subject to red-spider and green-fly, will not be attacked by either—if this manure is used in potting those plants.

"The foliage in every case is vastly improved, and the blossoms are more abundant, and the colour is intensified.

"Camellias will never require sponging, as the foliage will continue healthy, and the bloom-buds are not liable to drop off.

"Azaleas will not be attacked with red-spider, and where large plants are already attacked a good top-dressing will in about six weeks' time completely free the plants from the pest without dipping or syringing. You will rarely require to smoke, and if the manure is regularly used probably fumigating will never be needed. Please try for these results to satisfy yourselves."

— The NEW PYRAMIDAL LAURUSTINUS, sent out a short time since by Mr. KNIGHT, of Hailsbam, appears to be a very desirable evergreen, as it is not only stronger in growth than the old form, but it is much harder in constitution also. Mr. JOHN PERKINS, of Northampton, who is growing the new *Laurustinus* somewhat largely, states that while the common one gets cut up by frost in his nursery, the new one is unharmed. The flowers also are larger, and the individual trusses bolder in appearance.

— At the farm of Lin Mui, in Aberdeenshire, at 1300 feet elevation, there are several old ASH TREES, the two largest of which, in 1843, were 5 feet and 4 feet 2 inches in girth at the base respectively; in 1859 their girths were 5 feet 6 inches and 4 feet 4 inches. At HER MAJESTY'S Lodge at Loch Muic, 1350 feet above the sea, and 50 miles inland, where most of the ordinary culinary plants are grown, Bay and Portugal Laurels also succeed. There are

also thriving Larches, the girths of four of the largest, near the ground, were:—

No.	In 1843.	In 1859.
1	4 ft. 9 in.	5 ft. 7 in.
2	4 0	5 6
3	4 0	5 4
4	3 6	5 0

— We are glad to hear that an accession of nearly forty new members represents the number of new subscribers to the GARDENERS' ROYAL BENEVOLENT INSTITUTION, in consequence of Mr. CUTLER'S canvass at the Carlisle show and elsewhere. We are specially pleased to see that the new members are mostly representatives of the gardening class, either as nurserymen or as gardeners. It is not creditable that such an Institution should depend so much on the patronage of outsiders. We are satisfied that if the advantages of the Institution were more understood the number of members would be increased. Like other institutions, it is not perfect, but the way to improve it is to obtain an increase in the number of members, and for the existing members to take an active interest in the proceedings of the Society. We believe there is a good chance of a large addition to the number of pensioners at the next election.

— Dr. DICKIE, in a paper published in 1843 in the *Quarterly Journal of Agriculture* (xiii., 393), gives particulars of a large number of TREES IN ABERDEENSHIRE, from which the following are selected:—

	Girth at 4 feet from the ground.		Locality, &c.
	Ft.	in.	
<i>Pinus sylvestris</i> , Scotch Fir ..	13	7	Mar Forest—est. cubic contents, 250 feet (den
<i>Larix europæa</i> , Larch ..	10	1	Mar Lodge Gar-
<i>Abies excelsa</i> , Spruce Fir ..	10	6	Whitehaugh
<i>Abies pectinata</i> , Silver Fir ..	10	11	Stricthea
<i>Taxus baccata</i> , Yew ..	12	6	Ellon
	12	10	
<i>Quercus Robur</i> , Oak ..	12	9	Huntly Lodge
Do. ..	9	7	Ballater (natural Oak)
<i>Fagus sylvatica</i> , Beech ..	18	6	Crathes [Ellon]
<i>Castanea vulgaris</i> , Chestnut ..	11	10	Waterton (near Aboyne
<i>Tilia europæa</i> , Lime ..	9	8	Do.
<i>Fraxinus excelsior</i> , Ash ..	15	0	Do.
<i>Ulmus montana</i> , Scotch Elm ..	9	8	Craibston
<i>Acer Pseudo-platanus</i> , Sycamore ..	11	1	Glenkindy (Brae-
<i>Betula alba</i> , Birch ..	8	2	Craggan
<i>Alnus glutinosa</i> , Alder ..	7	5	Haddington
<i>Pyrus Aucuparia</i> , Rowan ..	6	3	Edinglassie
<i>Crataegus Oxyacantha</i> , Hawthorn ..	4	2	Leith Hall.
<i>Prunus Cerasus</i> , Cherry and Gean ..	7	6	Edinglassie.
<i>Populus tremula</i> , Aspen ..	6	10	Invercauld.
<i>Salix alba</i> , Huntingdon, Willow ..	8	4	Echt.
<i>Juglans regia</i> , Walnut ..	5	6	Crathes.
<i>Æsculus Hippocastanum</i> , Horse Chestnut ..	9	0	Do.
<i>Ilex Aquifolium</i> , Holly ..	5	9	Blackhall.

Professor BARLOW experimented on three specimens of Mar Forest Fir, one of which had been felled three years, another one year, and the third eight months. "Each of these trees was about 28 inches in diameter at the root, and contained 50 feet in length of serviceable timber—the grain remarkably clean, free from knots, and full of turpentine; and, from the results in the tables, it appears that the strength exceeds that of any other Fir that was submitted to experiment, although the second specimen of Riga was selected from a tree supposed to be of superior quality, on purpose to form a comparison."

— One very evident indication, to use a surgical term, afforded by Mr. WORTHINGTON SMITH'S discovery of the resting-spore of the Potato fungus and its mode of growth is not yet acted on by Potato growers as it ought to be. It takes a very long time for scientific information to be appreciated by practical men, even when it is of the greatest moment to them. It is clear, however, to those who will read Mr. SMITH'S observations that by the IMMEDIATE DESTRUCTION OF THE HAULM OF DISEASED POTATOS by fire the extension and propagation of the fungus might, to a very considerable extent, be arrested, while on the contrary our present carelessness in this matter affords the best possible opportunity for the perpetuation and dissemination of the plague.

— In accordance with our plan of publishing from time to time illustrations of our finer hardy trees and shrubs, especially of such as are not so well known as their merits entitle them to be, we now give a figure

of STUARTIA VIRGINICA (fig. 86). This is as to its flowers a noble shrub. It is a native of the Southern States of North America, and is as to its kinship a close ally of *Camellias* and the *Tea* plant. It was introduced according to LOUDON as far back as 1742, but is rarely met with in British shrubberies. Our illustration was taken from a plant which flowered in great profusion at Sion House, near Brentford, during the present season, and for specimens of which we are indebted to the kindness of Mr. WOODBRIDGE. A peaty soil, such as that generally used for "American plants," is most suitable, but we remember to have seen it in great beauty in the Canterbury Nurseries in a stiff loamy soil. The flowers in our illustration are of natural size. In colour they are creamy white, the very numerous filaments being of a purplish hue.

THE MILFORD NURSERIES.

To a lover or admirer of the beautiful, as it is found amongst hardy trees and shrubs, an occasional ramble through any of the great tree nurseries affords a singularly interesting treat and many an instructive lesson in dendrology. Since the spring of 1874, when Mr. Young's nursery was last noticed in this journal, we have many times had the pleasure of paying him a visit, and are indebted to him for much valuable information freely imparted to us. The characteristic features of the nursery have been alluded to before, and our readers will find at p. 410 of our vol. i., new series, a couple of admirable illustrations of views in the grounds. The series of "striking situations" then alluded to have been increased and improved, and it is astonishing to see how much may be done by skillful planting, even on a limited area, to make a place enjoyable. But our object now is not to descant upon such topics as this, but rather, as the planting season is at hand, to note some of the more rare and beautiful of the trees and shrubs which Mr. Young has gathered about him.

The first to make a note of is perhaps the finest of all the green-leaved Oaks—*Quercus laurifolia*, a native of America, with large broad and entire, dark green, shining leaves, which hang on the tree nearly all winter. It is a very free grower, and would make a handsome tree, but is not sought after half so much as it deserves to be. The fine bold golden-leaved *Quercus Concordia* was in fine form, and Mr. Young remarked that its foliage gets burnt less as the tree increases in age. *Q. Cerris pendula* is a weeping form of the Turkey Oak, a novelty remarkable for its pendulous habit and the silvery grey hue of its foliage. Another handsome-leaved Oak deserving the notice of planters is *Quercus conferta* (pannonica), and also *Q. fastigiata viridis*.

The beautiful Scarlet Oak, *Q. coccinea*, is too well known to require more than passing mention, but in the rich purple-leaved *Quercus nigra* we have a tree that is only just coming into notice, but, like the Copper Beech, it will make a grand object in the landscape, and afford a lively contrast to its scarlet and golden congeners.

There are many fine subjects for the landscape gardener amongst the Alders. The first that we note here is *Alnus incana variegata*, a new form that has not yet been sent out. The leaves when true to character are heavily blotched with yellow, but this character does not seem at present to be well fixed, as the plants occasionally hark back to the green state to break out again into golden variegation further on. In *Alnus glutinosa aurea* we have the variegation well fixed, and a very pleasing tree it is with its pure lemon-yellow leaves. *A. glutinosa imperialis* is a fine thing, with deeply cut leaves and elegant pendulous branches. *A. viridis* is remarkable for the dark green colour of its wood and foliage; and *A. cordata* for its fine heart-shaped leaves of a similar colour, and its fine habit of growth. The last named is sometimes called the Italian Alder, and is almost an evergreen, retaining its foliage well into the winter and spring.

A ramble amongst the Maples affords additional proof that the grandest of them all for landscape work is *Acer colchicum rubrum*, a good grower, whose ample foliage from spring till late in autumn is of a bright rosy purple colour. Next comes *Acer rubrum*, the red-flowered Maple, a most ornamental object, whether we regard it when in flower in spring, or later on, when its foliage assumes a rich purple and crimson hue of colour. *A. Wagneriana* (*eriocarpum*) is a cut-leaved form, a fast grower, and very ornamental. For planting near the seaside none of the *Acers* do so well as the Norway Maple, which is a rapid grower, stands the sea breeze well, and dies off a rich

golden-yellow in the autumn. A pretty and interesting tree is *A. saccharinum*, the Sugar or Bird's-eye Maple of North America. It is a smaller tree altogether than *A. rubrum* or *A. colchicum rubrum*, and less handsome than either; but "handsome is as handsome does," and this produces the most valuable timber. A fine broad-leaved form is *A. obtusatum*, but it is not a well-known plant, though introduced so far back as 1825. There is also here a pretty golden variegated variety of the Norway Maple, and also a golden form of the handsome so-called Corstorphine Plane.

The Spanish Chestnuts, too, are remarkably handsome trees, and we noted a curious variety of *Castanea vesca* named *heterophylla dissecta*, in which the leaves are divided into long narrow segments, giving the tree an elegant feathery appearance, and the beauty of which is enhanced by its silvery variegation. *Castanea chioquin* is a curiosity, while in *C. vesca laciniata*, with its deeply serrated foliage, and the variety named *marginata*, the leaves of which are margined with silver, Mr. Young has two fine novelties, which are associated with his own name.

The Judas tree, *Cercis siliquastrum*, is worth planting for the sake of variety. It is not a particularly handsome growing tree, but it has beautiful foliage, and produces its rosy-purple flowers in spring before the leaves are developed. *Koeleruteria paniculata* possesses similar characteristics, but it is a free flowerer, and its yellow blossoms have a grand appearance in June and July. The comparatively new *Catalpa syringifolia aurea*, if anything increases in beauty and value as it gains in age. It is very hardy, gets brighter in colour as the power of the sun is intensified, and has truly noble foliage. It is one of the very best arboreal subjects of late introduction, and is deserving of extensive planting for landscape effect.

Young's Weeping Beech, of which the original tree is such an interesting feature in the nursery, is so well known as to require no more than passing mention; but in the new Weeping Birch, *Betula alba pendula Youngii*, which was found growing in the neighbourhood of the nursery a few years ago, we have an elegant variety, that requires only to be better known to receive its due amount of appreciation. The cut-leaved Lime makes a beautiful tree as a standard, and is very pleasing also in the form of a pyramid.

The Golden Chinese Juniper, which also originated here, is met with in considerable quantities, and right well does it maintain the high character it gained when first introduced to public notice. It keeps its golden colour bright right through the winter, and grows with great freedom. The new variegated Tulip-tree, sent out by Van Houtte, and the leaves of which are margined with golden-yellow, also promises to make a very handsome tree. Those who are in search of bold-leaved bushy growing trees should make a note of *Magnolia acuminata* and *M. tripetala*. Their foliage here is of grand size, and the general contour of the bushes magnificent in the extreme. *Viburnum macrocephalum*, an introduction from the North of China, proves to be a very fine shrub, and has pure white flowers very freely produced. This and the glorious *V. plicatum* should find a place in every sheltered shrubbery border. The fastigate *Robinia* is remarkable for its pyramidal Lombardy Poplar style of growth, and occasionally produces golden-yellow leaves. We also found here some representatives of *Cornus florida*, an ornamental tree with obovate leaves, large white flowers and scarlet berries. It is a little known native of North America, but is said to be the finest of all, and to be seen in grand form at Rhode Island.

Of all the hardy golden-leaved shrubs yet introduced the golden-leaved Elder is, perhaps, the one that will prove the most accommodating; and, as has been said many times before, it is a most beautiful plant, and one that will in a short time produce great effect if planted on the margins of woods and plantations, or anywhere in view of carriage drives or wilderness walks, and yet, strange to say, it is a plant very seldom asked for. A free-growing, fine-foliaged tree is the new *Rhus Osbeckii*, and it has also the merit of producing large panicles of white blossoms. A fine companion plant to the golden-leaved Elder is the purple Hazel, whose rich dark bronze-coloured leaves would associate well with that bright and cheerful subject. The fringe of a wood would suit it to perfection; and another fine thing for a similar position is *Sorbus pinnatifida*, a large variety of the American Mountain Ash, and which produces very large clusters of berries. *Ulmus campestris aurea* is a

new Golden Elm, of which more will yet be heard; and in the weeping deciduous Cypress, *Taxodium distichum pendulum*, we have a form, which promises to make a good tree. There is a good example of this at Valentines, near Ilford. The old Weeping Cherry, now seldom seen, we also found here, together with a new pendulous variety, which produces an abundance of rosy white flowers in spring. Mr. Young has also in preparation for sending out a weeping form of one of the garden varieties of Cherry.

A thoroughly good free-flowering shrub is *Cotoneaster Wheeleri*, raised and sent out by Mr. Wheeler, of Warminster. The Silver Poplar planted in a mass strikes the eye at once as a glorious object in the landscape; and another tree which must make its mark in years to come, when it reaches its full proportions, is the Fern-leaved Beech, *Fagus asplenifolia*, a round-headed tree and a very fine thing. A curious subject amongst the Poplars is *Populus Tacamahac*, which somewhat resembles a pyramidal Pear tree in its habit of growth. *Carragana arborescens pendula* is not often met with, but on account of its fine yellow leguminous flowers should be more often planted. The handsome *Virgilia lutea*, or *Cladrastis lutea*, also claims passing mention, together with *Ulmus crispus*, a close pyramidal habited tree, with fringed copper-green leaves, and *Betula californica*, which retains its foliage till late in the autumn. Another little known tree which possesses the same characteristic is the stiff-leaved *Fagus ferruginea*. Did the exigencies of space permit it a great many more beautiful and useful subjects might be enumerated, for there is a fine variety of such subjects to be found here.

The nursery is particularly rich in Japanese plants, and amongst them we noted *Raphiolepis ovata*, an evergreen shrub with thick ovate leaves, and terminal clusters of very pretty small white flowers. *Aucubas* are a speciality, and so also are *Roses* of the *Manetti*, which exactly suits the sandy soil of this district; as a consequence an immense quantity of plants are worked on it, and a splendid growth they make. *Clematises* are also propagated in large quantities, and well grown too in large tubs, in which they flower with great profusion during the summer and autumn months. Forest trees are also turned out on extensive scale, and besides all these there are the usual quantity of fruit trees, and of such miscellaneous subjects as go to make up the stock-in-trade of a well ordered nursery.

Home Correspondence.

The Early Ascot Frontignan Grape.—Will you allow me again to call attention to the merits of the Early Ascot Frontignan Grape. In this backward season it has served us as well as usual. Its advantages as a Grape grown without artificial heat are with us that it ripens its fruit earlier, that its bunches and berries are larger, and its flavour much bigger than the other cold Grapes grown in the orchard-house with it. Messrs. Standish & Co., of Ascot, the raisers, have, at my request, sent a Vine to an artist in Surrey, a master of the art of growing and training hard Grapes over walls and roofs, so its merits as an outdoor Grape will now be fairly tested. The owner of Heckfield Place informed me that he intended growing this Grape in a vinery to see how heat developed the fruit; perhaps Mr. Wildsmith will, in your columns, tell with what results. *George F. Wilson.*

The Culture of Clerodendrons.—I should feel much obliged if Mr. Baines would give me a little information on the cultivation of *Clerodendron Balfourianum*. The usual time it flowers with me is in May, but I have seen it in good bloom at flower shows in August and September. Is this the second bloom, or is it the first bloom retarded? or how is it managed? *G. W.* [*Clerodendron Balfourianum* is one of the most manageable plants grown as to the time of its flowering, as it can be had in bloom from the beginning of April till September; it requires some special treatment to have it in flower very late. If a plant that bloomed in the spring—say in May—was wanted to come in the year following as late as August or the beginning of September, instead of starting it into growth immediately after flowering it should be cut back as far as necessary and kept in a moderately cool house for a couple of months, it should then be transferred to the stove, the young shoots trained close under the roof, and kept growing to the end of the year. Water should then be withheld till the leaves flag freely, when give a little, just so as to freshen up the foliage, but not enough to soak the soil, or it will in-

duce more growth. This checking process should be continued, letting the soil ultimately get quite dry, which will cause the leaves to die off. This will take about two months, when the plant should be removed to where it can be kept at from 55° to 60° in the night; it is not safe much lower than this. Here it may remain through March, April, and May, only just giving enough water to keep the bark from shrivelling. By this time it will show signs of wanting to make growth, when it may have a little warmth and the roots should be well soaked, but it must not be subjected to very strong heat, or it will come on too fast for the time it is required. Another method is to ripen a plant off early in the autumn that has been started soon in spring, give it a short rest and push it into flower, so as to have the bloom open during the winter, then let it make growth for two months, induce rest by withholding water, and again start into growth and it will flower through September. Or a plant that has been brought into bloom in May may after this be stood in a cool house, giving no more water than will keep the leaves from flagging to an extent that would destroy them; after this submit it to a brisk heat about seven or eight weeks before it is wanted in bloom. This *Clerodendron* may be had in flower late by any of these three methods, the first being probably the best. *T. B.]*

At what Depth should Bulbs be Planted?—This is a question of great interest to gardeners. My experience is decidedly in favour of deep planting for such bulbs as Winter Aconite, Crocus, Snowdrop, Narcissus, and Hyacinth. The depth should perhaps vary with the soil, being greatest in light open soils, but I have not found a foot above the crown of the bulb too much in any soil. The tendency of the Crocus, where not covered with turf, is to work upwards, new bulbs forming every year on the crown of the old bulb, but probably this tendency is counteracted in their natural state. In Nottingham meadows, where the blue Crocus is naturalised, I used often to dig them up, and think the average depth is about a foot. The surface of the ground is probably raised there by the alluvial deposit of floods faster than the new bulbs rise, but in getting up Snowdrops, Crocuses, or Daffodils which have been accidentally left wild, I have generally been surprised at the depth of the bulbs. In fields of stiff red clay in Cheshire the common double Daffodil flowers in luxuriant clumps, which I have wished to divide, and found that the full depth of a garden spade, 18 inches, does not reach the bulbs. The common autumn Crocus (*Colchicum autumnale*), which is perhaps native there, grows nearly as deep. Again, where garden ground has been dug deep, we see here and there a Crocus or Snowdrop which has been accidentally buried flowering quite as well as any others, and on taking it up to restore it to its proper place are surprised to find that not only is the bulb at least a foot deep but also upside down. The obvious advantage of deep planting in mixed borders is that spring bulbs so planted need not in any way interfere with such things as scarlet Pelargoniums or blue Lobelias planted over them, not to mention instances where gardeners who have not enough to do employ their superfluous time in autumn in digging the mixed herbaceous borders, an evil practice I have much difficulty in preventing. Of course the rule of deep planting does not apply to all bulbs, exceptions are Anemones, Cyclamens, &c. I believe that Hyacinths and Polyanthus Narcissus, where the soil is light, may with advantage be covered to a depth of 18 inches. *C. W. Dod.*

—In the autumn of 1869 Crocuses were extensively planted at Bicton from 4 inches to 5 inches deep. This proved a failure, from the raids of mice and rooks, which made large gaps of 1 foot and upwards in our lines and circles. The remaining bulbs when matured were lifted and stored in the usual way. The following autumn we made a bold attempt at deep planting; holes were made from 12 inches to 13 inches deep, the bulbs dropped in, and a pinch of soot thrown in upon each, and then filled in. After flowering, instead of lifting as before, the leaves were tied in knots (until properly ripened) for a twofold purpose, viz., for neatness, and to enable us to prepare for summer bedding, by which time the leaves would come readily away, leaving the bulb safe and intact for another season. This mode of treatment proved a decided success year after year, thereby saving a deal of labour and anxiety, and last, but not least, the censure of many that know but little of the many contending enemies the gardener meets with in every branch of his profession. *T. Shingle, Tortworth Gardens.*

Dr. Hogg Melon and Telegraph Cucumber.—I believe I have grown as many different kinds of Melons as there are weeks in the year, and my favourite out of all kinds is Dr. Hogg. It is decidedly handsome, and beautifully netted, the flesh green and tender, of excellent flavour, and keeping well after being cut. Added to this it has a fine constitution, and sets freely. This, I think, embraces all

the good qualities of a Melon. And now let me say that, after many trials of Cucumbers, I very much prefer the Telegraph to any other. Years ago I heard of a gentleman who grew nothing but Beechwood Melon and Sion House Cucumber; I wish I could make up my mind to follow his plan, and grow nothing but the Melon and Cucumber I have named. I know by so doing I should be saved from many disappointments. *J. Rust, Eridge Castle.*

Lesson on the Potato Disease.—In the article printed in the *Gardeners' Chronicle* of the 29th ult. is given an exhaustive description how the Potato disease is to be set at defiance for the future. For the last quarter of a century I have at different times in the columns of the *Gardeners' Chronicle* promulgated, from experiments in planting early ripening varieties of Potatos, so as to have them matured early in July, that they were safe from the disease, and that this system would be the only one to be depended on for the future. We have now in some of the early-ripening American sort of Potatos great croppers and with short haulm, and if these were crossed with some of our best early kinds new varieties of good flavour and keeping qualities might be raised for main crops. One variety, named Alpha, has with me this year ripened in the end of June, a great cropper of good size, but with the objectionable earthy flavour of some of these American sorts; but crosses from it might give us a round early Potato of good flavour. *Mona's Pride*, *Lee's Hammersmith Kidney*, *Feon's Early Market*, and some other early sorts, if planted as early as the season and soil will permit, can all be raised ripe enough for late keeping before any disease appears, let June and July be ever so wet. There will doubtless be many growers of Potatos still planting them at the usual time and trusting to the chance of a dry, warm summer; but to make the risk less, if they were to plant them in alternate rows with root crops the loss then would not be so great as in years like the present. In the case of some of the strogg-growing kinds of Potatos, with hard, woody haulm and leathery, red skins, the fungus seems to attack them very slowly, but they cannot be said to be disease-proof. One kind I grew here, and received under the name of *Millett Manifold*, is yet quite green and growing, although every kind in the garden near it has its haulm dead. Another seedling raised from it, and set out under the name of *Wood's Scarlet Prolific*, has the same property of resisting the disease in both haulm and tubers. The *Red-skinned Flourball* and a red kidney variety I had from Prussia two or three years ago, both belong to this section; and all of them, if planted so as to ripen before the frosts attack them in October, would produce good crops. These varieties are not the best for table use, but they keep well, and their flavour is much improved by growing them on light soils without much manure. By growing our main Potato crops very early, or very late, the fungus would gradually be starved out for want of a suitable place for its resting-spores, whether in the soil, on the haulm, or on decaying tubers. As the critical stage of the disease appearing on the main crops of Potatos is in a certain period of their growth, and this is generally in the end of July or in August, an experienced watcher of the disease can tell in a few days when it will appear, should the weather be moist and the temperature high, and it is more quickly developed during thunder showers if the air is close and sultry; not that electricity has anything to do as the cause of it, but only that it favours the development of the fungus in huddery weather, when the temperature is high and heavy showers are falling. *William Tillery.*

The Vicomtesse Héricart de Thury Strawberry.—Mr. Harrison Weir, p. 373, makes rather a singular mistake in referring to my article on Strawberries (p. 10, Fruit Supplement), inasmuch as I did not even name the variety he mentions—Vicomtesse Héricart de Thury—which is a good forcer, but one that I should not grow out-of-doors only in exceptional situations. *Z.*

The Lathyrus as a Town Plant.—The above named leguminous plants form a very numerous group, of which the Sweet Pea is a familiar example. The perennial species, or "everlasting Peas," are charming things, but seldom seen in the right place; all attempts at staking, training, or tying-up with these plants are absurd: they must have, to look well, their own will and their own way. Nothing can exceed the beauty of *L. grandiflorus* rambling over a rough stony bank or among the broken masses in an old stone quarry. It has often struck me that the proper place for climbing plants of this tribe would be the divisional raising dividing the front gardens attached to the houses on the outskirts of most of our large towns; the perennial plants of this section are just suited for such places. Thriving luxuriantly in any place or in any kind of soil, establishing themselves wherever a bit of a root can be thrust in among paving-stones or flags, and left to ramble at will among the light divisional fences

above alluded to, the effect would be charming; not a nail or a tie would be necessary—all the care required would be to interlace the main shoots as they grow on the fence and leave them alone. In such a situation they would make themselves at home, and make a display such as is never seen when the plants are tied up, besom-fashion, round the bole of a tree. In addition to the sorts commonly grown, such as *L. graediflorus*, *rotundifolius*, *latifolius*, and its white var., the best of all, and the most vigorous grower, is a little known species, *L. pyrenaicus*, sometimes called *venosus*. *T. Williams, Ormskirk.*

Orchids in September.—I find that this monthly list is tempting many to indulge in Orchid-growing. It is, perhaps, right to inform them that the number it exhibits is due to a personal interest I take in Nature's varieties as well as in Nature's beauties, and consequently mine aims rather at being a collection than a selection. Many that appear there are more of botanical than of floral interest. Beginners should not be guided by these alone, but consult Mr. Williams' book for the most serviceable of them. The list is, however, useful by showing what we may look for in each month. To the regular Orchid-growers it has an interest of another kind.

I have received many communications relative to the *Odontoglossum* described in my last as *angustatum*; and it has been shown to several experienced Orchid growers, but has been recognised only by Sir Trevor Lawrence, who informs me that it once flowered in his fine collection, and was sent to Professor Reichenbach, who pronounced it to be new, and gave to it the name of *O. linguiforme*. Even so experienced a man as Mr. Dominy had never seen it. All agree that it is not *angustatum*, which, they say, has a short stalk. It was, however, bought both by Sir T. Lawrence and myself by that name. I have a second plant of it in flower bought under the name of *O. distans*, which it certainly is not, if another plant so-called be true, and which is just now sending up four long stalks. At all events, it deserves extensive cultivation, not so much for beauty and the individual flowers as for their profusion, their long lasting, their unusual colour, and the general effect of the mass; but do not wind them round sticks, let them turn and twist among the leaves of the surrounding plants, as they obviously love to do, and in which position the branchlets creep out from among the leaves and display their flowers with a grace that is in itself a new charm. So it should be with all the long-stemmed Orchids—*Oncidium macranthum*, for instance. It is often objected to them that the flowers are so far apart, but Nature has so ordered it for an obvious purpose. They grow among other loftier vegetation. The flower-stem is long because the flowers must rise above their surroundings to attract the fertilising insects. Each branchlet peers from out the foliage, or hangs over the projecting rock or stump, and thus its whole beauty is shown to the day. No person who has once observed the effect of allowing the stems to lie at length among the surrounding plants with the branchlets throwing out their blooms at intervals, will ever again attempt to twist a flower-stem round a stick. *Edward W. Cox, Mount Mount, Mill Hill, N.W., October 1.*

Pumpkin Preserve.—Except that your correspondent, "S. W.," advocates the making of preserve from the Pumpkin instead of from the Vegetable Marrow, his advice adds but little to what I last year put before your readers with respect to the excellence of Vegetable Marrow preserve. This delicious compound has been made in several ways in our household this autumn, in each case with success, the chief result being that all who taste it wish heartily that they had made a store of it, whilst it is impossible to feel other than regret that so many households are de-

prived of a cheap and wholesome jam solely through ignorance of its quality, and the method of producing it. The Gourd alluded to by your correspondent is probably the same as is sold in the seed trade under the name of the Ohio Squash; it is also well-known in the South as the Vegetable Cream Marrow. The flesh is thick, yellow, and of soft, marrowy texture; the fruit large and egg-shaped, and certainly the best of all kinds for cooking when ripe. It is, however, much less prolific than good kinds of the Vegetable Marrow, and for that reason, and also because it has such yellow flesh, it is not appreciated generally in gardens. The best Marrow in my judgment for preserving purposes is the long deep green kind known as the Cucumber Marrow. It has thick white flesh of great solidity free from the stringiness so common in the white Marrow, and these good qualities render it specially suitable for preserving purposes. It is not less a first-rate kind for ordinary table uses. The fruit are best for preserving when well matured, but prior to the rind becoming hard good fruit of this kind at this stage when cut up will yield from 8 to 9 lb. of fruit for boiling. The colour of this Marrow preserve is not so deep as is that made from the yellow kind, but colour in the case of an ordinary preserve is of little moment: it is enough that it is bright, clear, and pleasant. Two forms of preserve are made from the Marrow—one to represent preserved ginger, and to be used with the dessert; the other to be used as an ordinary domestic preserve. To make the first the Marrow flesh is cut into pieces about 1 inch by ½ inch, and the sugar, in the proportion of ¾ lb. to the pound of Marrow, is put in with the Marrow. This causes the pieces to become firm, and when boiled for about 1½ to 2 hours it is thoroughly done. To produce the illusion of mock ginger a considerable proportion of ground ginger is boiled in with it, and the rind of a Lemon or more, according to quantity, is sliced up thinly, and the juice pressed into the preserve, and this adds a delicious flavour. For ordinary preserve it is found best to cut the Marrow flesh up quite small and place it in a large jar, adding a sprinkling of moist sugar. When this has stood twenty-four hours it is found that a considerable portion of water has been extracted, and that the Marrow is much sweetened. To this is added about half-a-pound of sugar to the pound of fruit, the Marrow being boiled half-an-hour before the sugar is added. A slight flavouring of ground ginger and essence of lemon, both very inexpensive things, are all the additions necessary to produce a delicious wholesome preserve. Where Marrows are cultivated it is probable that this jam can be made for the small cost of about 2d. per lb., a fact that should force itself upon the attention of housewives in these days of dear butter. From Rhubarb, Apples, and even Carrots, really nice wholesome preserve can be made, but probably the cheapest and most available material is Vegetable Marrow, as it is a plant that can be induced to grow almost anywhere. *Alex Dean, Bedford.*

Burning Clay.—I several years ago burnt a large quantity of clay, both to improve the tilth of my garden, which is a strong clay, and also in the fields, which I was preparing to be laid down to permanent grass. It is difficult to estimate the cost. Small cheap coals, with small cinders from the coke ovens, were used as fuel; the men had no practical training, and took advantage generally not to overwork themselves. I can't give an opinion of the effect upon the garden crops, as the land was just rich old grass broken up, and was therefore very productive; but upon a few acres of old tillage, which from previously having been renewable leasehold had been treated unjustly as to the supply of its fair share of manure, I found for years after the clay was burnt and worked into the top soil that the parts newly sown down to permanent grass not only showed in early spring the first growth of greenness, but generally presented to the eye an improved appearance to that portion of the crop adjoining; but my impression, and it is only a very superficial one, was that the process did not pay, or I should have more extensively pursued it. I obtained the clay by turning up to the surface a couple of inches or so of the clay with the plough, and then collecting it into good sized heaps with carts, and again, after being burnt, loading and spreading it over the land, where it was worked by plough and harrow among the top soil. The simple matter to be attended to is, that for this manuring and improvement of the condition of the land the clay must not be dry, or it will burn hard like a brick, and not swell, which it should do, so as to fall and moulder, to more perfectly mix with the soil. It must not be too much burnt. No doubt in my own case the magnesium lime, which considerably pervades my clay, not only as shown by the bluish separation in the clay, but also by small pieces of limestone mixed with it, and this, being by the heat converted into lime, would have some manurial value. We all know that yellow clay, from its want of lime, is of a very poor agricultural worth. To really arrive at the

benefit derivable from burning clay not only the expense but the discipline of clays are elements demanding special attention. To form new or repair existing farm roads the clay must be dried in suitable lumps before being burnt, and then the fire cannot be too rapidly forced to secure the full effect of the fuel; to keep a heap of dry lumps of clay smouldering for days without ever getting to the required degree of heat is like simmering a kettle, which will never thus boil, or like some men who will not follow up at a few days' interval dressing sheep's feet suffering from foot-root, or dressing sheep with scab at very short intervals, as the first dressing may kill all the acari but not destroy the eggs, which will soon hatch, and if not at once killed by a dressing form a new centre for the continuance of the disease. *W. A. Wooler.*

Scammony.—At p. 370 you call attention to the decreased supply and inferiority of the drug. The same remarks would generally apply to Jalap. It is well known in the medical profession and amongst drug manufacturers that it is almost impossible to get a sufficient supply of the pure drug, and thus several species of roots belonging to the nat. order Convolvulaceæ are imported as substitutes, but are very inferior to the true article, consequently, as is well known by most medical men, the action of those two drugs is very uncertain. I have long thought it possible that both those drugs could be profitably cultivated in this country, particularly in the warm sandy soils of Bedfordshire and elsewhere. Both the plants are perfectly hardy, of rapid growth, and would require but little care in their cultivation. Jalap is readily propagated by cuttings of the underground stem, or cutting up small tubers. It flowers freely late in autumn, but too late to produce seeds in quantity. The flowers are extremely beautiful, bright rosy purple. Scammony grows very freely, and produces its neat, creamy white flowers in the greatest abundance for several successive months, and matures its seed, from which young plants could be readily produced. The roots penetrate deeply into the ground, are somewhat in the way of the Parsnip but more branching, sometimes measuring as much as 18 inches or 2 feet long and 2½ inches in diameter. Last season the Scammony produced seed very freely, but I fear, owing to the rainy weather we have had so much of late, these will not be much good this season. Quite two-thirds of the drug Rhubarb is grown and manufactured in this country, and is equally efficacious as the best East Indian, and this led me to believe that Scammony and Jalap can be well and profitably grown in this country. *F. Tyerman.*

The Flora of St. Helena.—I have read with the greatest interest in the *Journal* of the Horticultural Society, Mr. Vernon Wollaston's admirable paper on the importance of preserving the almost extinct arborescent *Compositæ* of the Island of St. Helena. I sincerely trust that the hints he throws out may be taken, and his suggestions promptly and energetically carried out. I have just returned from a visit to my friend Mr. Dorrien Smith, at Tresco Abbey, in the Isles of Scilly. In his beautiful garden I saw *Aster argyrophyllus* and *Eurybia myrsinoides* growing with the greatest luxuriance, and making themselves as much at home as if in their native soil. I have no doubt that *Aster Burchelli* and *gummiferus* and all the other arborescent *Compositæ* of St. Helena would grow equally well in the gardens at Tresco Abbey, and I would suggest to Mr. Wollaston that he should at once if possible cause rooted cuttings to be forwarded to Mr. Dorrien Smith, by whom they would be cordially welcomed, and tended with the utmost care by his gardener, Mr. Vallance. Mr. Dorrien Smith is most anxious to receive from any part of the world such plants and bulbs as are likely to flourish in his most favourable climate and singularly interesting garden. *H. Harpur-Crewe.*

Orchids in Flower in Belgium.—The following Orchids are now in flower in M. Massange's collection, at the Château de Baillonville, near Liège, gardener M. Wilcke:—*Cypripedium niveum*, *Ashburtonia*, *Dayanum*, *Pearcei*, *Rozellii*, *Parishii*, *superbiens*, *barbatum*, *longifolium*; *Miltonia Moreliana*, *Lamarckiana*, *Clowesi*; *Odontoglossum vexillarium*, *chlandium*, *grande*, *erubescens*; *Zygopetalum Gaultieri*; *Masdevallia ignea*; *Oncidium pelicanum*, *nodosum* (*Kramerianum*), *cucullatum*, *arosum*, *Lanceanum*, *sarcodes*; *Lælia crispa*; *Mesospindium vulcanicum*; *Coleogyne assamica*, *speciosa*; *Epidendrum ciliare*, *vitellinum*; *Restrepia elegans*, *antennifer*; *Calanthe Masuca*; *Stanhopea Lindleyana*; *Vanda suavis* (*Veitchii*), *tricolor*, *tricolor flavescens*, *cinnamomea* and *Schilleriana* (which seem to be identical); *Batemanni*, *Lowii*, *undulata*; *Aerides quinquevulnera*; *Phalænopsis rosea*. The most beautiful plants are *Lælia Pinellii*, and a violet coloured variety of *Cattleya Harrisonæ*. The finest is a *Vanda cœrulea*, with eight flowers which measure nearly 5 inches across, larger than have been previously seen in Belgium. *E. M.*

Silk Culture in Great Britain.—The following are the temperatures, &c., concluded from p. 53. The first table gives the temperatures in my silk-

worm room, with observations for week ending July 2, 1877. It will be noticed that rainy weather greatly preponderated this season:—

	Minimum during Night.	7 A.M.	9 A.M.	12, noon.	3 P.M.	6 P.M.	9 P.M.	Hygro-meter.	Wind.	Rain.	Baro-meter.	Fire.	Observations.
June 26 ..	61	62	65	66	67	66	66	-4½	S.W., slight	Slight rain during day	30.0	None	
" 27 ..	61	62	68	73	70	70	68	-5	S.W., slight	Slight during day	30.0	Fire lighted because of the rain and dullness of the day	
" 28 ..	61	63	65	70	73	73	72	-4	N.W., slight	Fine	30.2	None	
" 29 ..	67	68	69	72	70	70	73	-3	W., slight	Fine	30.2	None	
" 30 ..	66	67	70	72	71	70	69	-2	N.E., slight	Fine	30.2	None	
July 1 ..	66	67	68	68	67	67	72	-5	N.W., slight	Rain at mid-day	29.9	Fire lighted in evening at 6 P.M.	Cool dull morning
" 2 ..	63	64	68	70	70	68	72	-6	W., slight	Rain during day, sunshiny and moist	30.0	Fire lighted evening at 8.30 P.M.	

Vers zebres are large and handsome, commencing their fourth age, of a rich chocolate-brown colour, with lighter markings; the worms of my own stock are in their third age approaching their third moult, are fine and feeding well, and so far very healthy. In consequence of the showery weather the fire has occasionally been lit, to dry the air in the *mag-nanerie* and prevent the bed of the silkworms from

being damp; the unconsumed food in which the worms repose being, if not thoroughly dried, a fruitful source of disease. We have to-day commenced the use of the leaf-cutting machine, which greatly economises labour in preparing the leaves as food for the worms. Owing to the showery weather the shoots on the Mulberry trees have grown much the past week.

Vers zebres have changed for their last time, and are very handsome. Brienza race feeding well, all fine; have changed for the third time; very healthy. Fire has been kept up, especially at night, during the change, as the weather was showery and cool, in

order to dry up the bed and prevent exhalation. Leaves on the Black Mulberry are now large and full-grown; on the White Mulberry the shoots are 2 feet long, and the leaves about two-thirds their full size.

Vers zebres are now beginning to wander about previous to cocooning. About six have begun their cocoons. They are not so healthy a race as the Brienza, a large proportion having died during these months from flaccidity, and a few from jaundice. The other worms continue very healthy, notwithstanding

the rainy moist weather, to counteract which, and dry the beds thoroughly during their change, a fire has been lighted nearly every night. They have now mostly passed their last moult and entered their fifth age, and are very voracious; all the small and weakly looking worms have been weeded out.

TEMPERATURES OF THE SILKWORM ROOM.

On these days and nights fire was kept in to dry the beds.

Observations.—The education has progressed very satisfactorily; a fire was continued till the 29th, to dry the beds and create free ventilation as the worms approached the spinning-time. The bushes were put up for the worms to spin their cocoons in on the 23d, when the first worms went up to spin. The cocoons are now all finished with the exception of a few laggards, which will be disregarded. Health has

continued excellent throughout till about the 23d, when showers became very frequent, the hygrometer went up to 8°, and the food came in damp. After that some jaundice was observed among the later worms, and some died soft (*mus*). *Derangement*, or the taking down of the cocoons and sorting them, was commenced August 1. The cocoons were much finer than those of last year.

This was all very well, but before I could go away she opened her apron, which was thrown, as it were, carelessly to one side, and showed that it was filled with cloths—dusters, or similar things. These she took out one by one, shook them, and tucked them into some kind of waistband, so that they all lay flat in front of her dress, and when they were safely fixed the large apron was put in its place, well patted down and pulled out at the sides, and she walked away. Just now, when autumn fruits and vegetables give an excuse for these intrusions, this very unpleasant observation may possibly be of some service. The fruit or vegetables make an excuse for admission into the kitchens of the unwary, and, once there, the basket or the apron apparently carelessly flung over the arm, are ready to receive anything within reach. Probably but for strict orders with regard to closed doors my unwelcome visitor would have also added some of my kitchen goods to her stores, and though where there was no positive proof of theft one might be excused in not drawing the attention of the police to the concealed goods, still a note of the method of concealment may be useful to some other *Suburban Resident*.

White Blackberries.—Can you or any of your large circle of correspondents inform me if they ever saw or heard of white Blackberries, or, in more common phrasology, white Bramble berries? A plant has been found here with beautiful white fruit, and the berries, which I tasted last night, had a delicious flavour. It would be a most desirable fruit for dessert purposes, and in my opinion is quite a novelty. *Wm. Bowman, Hylands Park, Chelmsford.*

How to Winter Begonia Tubers.—At p. 411 are some instructions about keeping tuberous Begonias through the winter, but allow me to say that those instructions are all wrong. Your correspondent says a dry greenhouse shelf would be a good place to keep them on; now this would on the contrary be a very bad place: these tubers through the winter require to be cool and comfortable, they keep very well in the pots in which they have been grown, stood upon a damp soil surface where the pots will absorb sufficient moisture to prevent them becoming dust-dry—just those conditions where the tubers and even some of the small rootlets would keep fresh and plump. Kept in this way they start strongly and naturally in the spring, and much earlier than when they have been kept dry. Many places would no doubt suggest themselves: a vault or cellar where frost was just excluded would be a capital place; the one thing they do not like is over drying, and it is from this cause alone that so many of the Continental bulbs are either slow to start or refuse altogether to grow. These are such beautiful plants, and really so little is generally known about their requirements, that I have been induced to write this. I have a house now with about 3000 plants all in flower, and of every imaginable shade of colour and style of growth, in fact it is quite safe to say that no more beautiful floral sight could be found. *T. Smith, Newark.*

Rose-coloured Mimulus.—Can any of your readers tell me what has become of an old favourite which I bought twenty years ago for sixpence at a country nursery garden under the name of *Mimulus Reidi*? Its foliage and habit resembled *M. cardinalis*, but the flower was of better form and substance, and of a cheerful light rose colour. I kept it for many years, and gave many to my friends, but it entirely disappeared from all our gardens in the hot and dry summer of 1865. When I had it once saw it in a little garden in Praed Street, Paddington, but have never been able to hear of it anywhere since. *C. W. Dod, Eton.*

Tuberous Begonias.—*Begonia octopetala* did very well here this summer, and formed a pretty tuft on a raised bed, the soil light loam and peat, and a few stones added for drainage. *B. Frœbelli* never started at all with the same treatment, and *B. boliviensis* did well on the same bed. *B. octopetala* forms a nice tuft with its angular leaves, it bore one or two spikes of white flowers on transparent red stalks. The plants came from Mr. Ware at Tottenham, and were planted out the second week in June, and were not protected in the very cold weather, which came late in the season. They were well supplied with water, the raised bed in this soil being necessarily dry, and they also enjoyed the overflowings of the liquid manure given to the *Maréchal Niel* Rose, which forms the centre of the bed, this last about once a-week. *H. M. E., Newbold.*

The Flow of the Sap.—In his remarks at page 339, on my communication (p. 309) on this subject, your correspondent "D," whilst commenting on my views on the flow of the sap, has unfortunately overlooked my reasons for holding them, as for example

Fourth moult	July 6-12	" 11-18
Spinning	" 16-23	" 22-29
Emerged from cocoon	Aug. 3-10	Aug. 9-23

Observations.—On July 16 and 17, the *vers zebra* began to spin golden cocoons, very stout, of good quality, firm and fine. I obtained in all ninety-six cocoons, of these the first emerged on Aug. 3, and the bulk on the 7th, 8th, and 9th. The moths laid from 500 to 650 eggs each. On July 22d up to the 29th the bulk (Roland's race) began to spin cocoons of a pale buff colour. Bunches of Broom, freshly cut and dried, were placed round three sides of the trays, and in these the worms mounted and spun their cocoons—white at first, but changing in about three days to the deeper tint. During all this time a fire was necessary, not merely for the purpose of ventilation, and to dry the beds—which at that time are very moist with the last purgings of the worms—but also because a high temperature makes the worm discharge his thread more easily, a lower temperature chilling the gum. On August 15 moths began to emerge. About August 1 the *derangement* commenced, which consists in taking down the Broom bushes from the trays, picking out the cocoons, divesting them of the loose silk, and separating them into three classes. Class 1 consisted of the best-shaped and stoutest cocoons; of these there were 1500. Class 2 consisted of the remaining good, well-shaped cocoons; of these there were about 9500. Class 3 consisted of thin-pointed, badly-shaped cocoons, which were rejected as inferior, and unsuitable for breeding from. The trays were then thoroughly cleared of all loose silk, refuse material, and the cocoons again laid thereon on brown paper sheets, and on August 12 they began to emerge, and continued to do so in quantity till the 19th. The bulk were then out, and after the 23d only 200 remained without having produced moths—a very small proportion. The moths emerged mainly during the night. At first there were many more females than males, but this was reversed later on. The males began to emerge about 11 P.M., so that at 6 A.M. we found many moths already paired. This continued up to 9 A.M., after which only a few moths came out during the day. The coupled pairs were placed on newspapers in a quiet place during the day, and about 4 P.M. to 6 P.M. were placed on the cards (straw-boards, about 11 x 8 inches), to deposit their

eggs. The males were removed later on in the evening and early the next morning. The females generally laid their eggs very quickly, and in large quantity—up to 300 or 400 each the first night, and from 100 to 200 more in succeeding nights. They would live a week were they not given to the chickens, who are very partial to them. It is desirable that each card should be covered with eggs in one night, *i.e.*, that uniformity as to time might be commenced with, and therefore it is well to crowd the board with as many females as possible, removing them to another tray as soon as sufficient eggs have been laid. The moths kept us very busy for about eight days, but after the 21st the work was well nigh finished. We obtained 5 oz. of loose eggs, and 36.22 grammes of eggs on card or straw-board; total, 41.22 oz., each ounce weighing 25 grammes. This education was very successful, notwithstanding a somewhat cool summer, with rain very frequently; our temperatures were kept very evenly from 65° to 75°, and the hygrometer low; the worms fed well; there were few laggards, no appearance of pebrine, and a much smaller number of jaundiced worms than in former seasons. They kept their time very evenly—about five days in hatching out from the eggs, and about eight days in cocooning and emerging as moths between the earliest and latest. There were very few cocoons that did not emerge, and the majority were well-formed, stout, and of good texture. Our labour consisted of myself and two boys of sixteen and seventeen, who were employed on an average, for half the time, half a day each, and for the remainder of the time a quarter of a day each; add to which the labour of two other boys, about a quarter of a day each, to gather the leaf. We stripped the foliage from six large Mulberry trees. Averaging the value of the eggs at 15s. per oz., the result would be a little over £30, plus the refuse material. Our White Mulberry trees have had a rest this season, and been well pruned; have since made good growth, many have shoots from 4 feet to 6 feet long, and promise well for next season. *Alex. Wallace, Colchester, September 19.*

Basket Vegetable Sellers.—All prudent housekeepers know the importance of keeping basket-women out of their houses, but still a singular scene, which I most unexpectedly saw going on at my own back door, may explain occasional mysterious disappearances. Having heard a ring, and the usual dismissal through the (unopened) glass garden door not being followed by the sound of retreating footsteps, I looked from an upper window to see what course the visitor might be proceeding on, and just below, screened from all known observation, stood a vegetable seller quietly inspecting something in her basket.

when he says that "he ('A.') assumes that the results of the ringing prove the ascent of the sap of no considerable amount by the bark." He is correct in thus stating my view on this point, but at the same time he seems to throw some doubt on it by adding, "Now it is a curious fact, if such is the case, that that peculiar excrescence-like growth of bark which is seen at the bottom of the upper bark is not seen at the top of the lower bark, and the same is found in all cases of ringing." In my former remarks I drew attention to this particular result of ringing by stating "that from the sections of the stem (see cuts, p. 309) it will be observed that no growth took place upwards from the bottom of either ring, and that the bark from the bottom of these rings downwards to the next lateral branches, is quite dead; showing that no sap can ascend in the bark without the pumping action of the leaves." When the rings were cut, of course it is apparent to any one that the bark below to the next branches was deprived of the action of the leaves. Towards the end of his notes "D." further remarks: "It would appear that 'A.' deduces from the general diminution of growth above the ring in the bark during the three years his experiment was being tested, that it is proof of the partial ascent of the sap through the bark; but if such be the case, is it not marvellous that not only did the tree above exist, but also continue to make growth of any kind." In supposing that part of the sap does ascend by the bark, I was led to that conclusion; first, because of the decaying of the bark between the bottom of the rings made on the stem, and the next branches below, as already stated; and, secondly, on account of the decrease in the growth of the whole tree immediately observable after these rings were removed. The reason why the tree continued to live and make some growth after the cutting of the bark was, I believe, that the sap ascended by the internal portion of the stem. "D." asks if the supposition that "the saps-vessels above the ring become gradually choked, and thus the starved growth" could not be accepted as the cause of the diminished growth? If this explanation be correct, it would be interesting to know how the sap got above the choked vessels to keep the tree in life, and enable it to form a new layer of wood each year. A.

The Fruit Crops.—The sorts of Apples that are bearing well here this year, out of a large collection, are the Afriston, Cellini, Devonshire, Buckland, Hoary Morning, Hawthornden, Manks' Codlin, and Yorkshire Greening. Of Pears the only sort bearing a good crop is Hessele, and a few Ne Plus Meuris. *Charles Clissold, Perry Hall, Birmingham.*

Ampelopsis Veitchii.—This is one of the most attractive plants imaginable at the present time, that is if the term can be applied to a plant at the time for shedding its leaves. It seems unnatural to be pleased in the appearance of the process of the fading of the leaf, but this subject may be quite distinctly placed amongst exceptions to that rule. The colours of the leaves of this climber just now are really beautiful. The soil is not over rich, consequently the leaves are not large, which is all the better, the wall being quite covered with nice small leaves. When the soil is rich the leaves of this plant will be as large, or nearly so, as the ordinary Virginian Vine. I saw such a plant with vigorous foliage in this neighbourhood, and I believe you made a note about one also being vigorous in the Temperate-house at Kew recently in your journal. If this *Ampelopsis* (*Veitchii*) was an evergreen it would be one of the very best of climbers for decorating walls and such places with, but being without leaves during the winter months is against its being planted largely. This I have proved by planting about a score of plants a few years ago. In summer, in a green state, it is a first-rate wall plant, in autumn it is at its best as a decorative plant, but in winter it shows its nakedness, and is far behind the Ivy and its varieties. I send you a few flowers of this plant, which may interest you. Pieces of wall are here densely covered with leaves, some as enclosed, and, excepting when first planted, they have had little or no attention as regards nailing. *Robert MacKellar.* [Nailing is not required, as it holds fast without. Eds.]

Strawberries.—I am getting a very fine lot of fruit from plants of Black Prince, which were forced in the spring. They were kept in pots all the summer, and three weeks ago, when showing abundance of flower, were put in a cold frame. My object in writing of this good old sort is to recommend it for autumn work, as producing a good supply. Of course I am aware that forced plants are generally planted out and a few gathered in a fine autumn, but not in such quantity and quality as when treated as I have described. British Queen, Keens' Seedling, and Vicomtesse Hélicart de Thury were forced, but showed scarcely any flower. *Charles Clissold, Perry Hall, Birmingham.*

Notices of Books.

The Locust Plague, &c. By Charles V. Riley, M.A. Chicago: Rand, McNally & Co.

Dr. Riley has published in a collected form his papers on the locust plague of West America. The Rocky Mountain locust, or so-called grasshopper, occurs in some of the Western States of America in such abundance as to obscure the light of the sun, and is so ruinously destructive as to devour almost every green thing that grows. Their distribution in America, roughly speaking, is confined to the treeless plains between the Rocky Mountains and the Mississippi. Some idea of their numbers may be obtained by the fact that travellers by rail passed for the better part of two days through a perfect storm of these insects, which frequently impeded or stopped the train by their crushed bodies. Nothing can surpass the prophet Joel's account of the appearance and ravages of these insects.

"A day of darkness and of gloominess, a day of clouds and of thick darkness, as the morning spread upon the mountains: a great people and a strong: there hath not been ever the like, neither shall be any more after it, even to the years of many generations. A fire devoureth before them, and behind them a flame burneth: the land is as the garden of Eden before them, and behind them a desolate wilderness; yea, and nothing shall escape them. The appearance of them is as the appearance of horses; and as horsemen so shall they run. Like the noise of chariots on the tops of mountains shall they leap, like the noise of a flame of fire that devoureth the stubble, as a strong people set in battle array. Before their face the people shall be much pained; all faces shall gather blackness. They shall run like mighty men, they shall climb the wall like men of war; and they shall march every one on his ways, and they shall not break their ranks. . . . They shall turn to and fro in the city; they shall run upon the wall, they shall climb up upon the houses; they shall enter in at the windows like a thief."

There is no evil without some compensating good. The destruction of food by the locusts brings about a scarcity of other insects in the following season, while the rich coating of manure left by the locusts causes the soil to be unusually productive.

One of the most curious phenomena observed in consequence of the Invasion of locusts is a change in the nature of the vegetation.

"Plants that in ordinary seasons are scarcely noticed become," says Dr. Riley, "extremely prevalent. *Amaranthus blitum* spread at an unprecedented rate and grew in great luxuriance after an incursion of locusts; so also the common Purslane started everywhere, and usurped the place of many others species. The common Nettle, *Solanum carolinense*, and the Sand Burr, *S. rostratum*, spread in 1875 to an alarming degree, and the Pokeweed, *Phytolacca decandra*, was very abundant. All kinds of grasses grew very luxuriantly during the summer, a fact due to the wet and favourable weather, but some kinds that are rare in ordinary seasons got the start, and grew in great strength and endurance. Professor Broadhead mentions more particularly *Aristida oligostachya*, in ordinary seasons of rare occurrence in the locality, as reaching the unusual height of a feet, and being very abundant. *Eragrostis pœooides*, ordinarily recumbent and scarcely noticeable, grew in profusion 3½ feet high, looking like meadows ready to be mowed. *Panicum sanguinale* was luxuriant enough to be cut for hay. Among these grasses none are more notable than the sudden appearance very generally over the locust devastated region of what is usually called a new grass springing up wherever the Blue-grass gets killed out; it proves a godsend to the people, for while it is young and tender cattle like it and fatten upon it. This grass is the *Vilfa vaginiiflora*, an annual which is common from the Atlantic to the Rocky Mountains. Unnoticed during ordinary seasons the destruction of the Blue-grass and other plants by the too close gnawing of the locusts gives it the advantage in the struggle for existence, an advantage which is soon

lost, however, as the normal relations between species are assumed again in a few years after the disturbing influence has ceased to be operative."

The best means of combating these locusts is to destroy the eggs, which are deposited just beneath the surface of the soil; ploughing and harrowing form the best means of destroying them. The quotations we have given will suffice to show the very great interest attaching to this little volume.

Introduction to Botanic Teachings at the Schools of Victoria, through References to Leading Native Plants. By Baron Ferdinand von Mueller. Melbourne: Ferres. 1877.

The industry and zeal of Baron von Mueller are beyond praise. Nothing damps his ardour. Adverse circumstances do but supply fresh fuel to his enthusiasm, and so we find him constantly engaged in some way or another in promoting scientific and practical botany, to the benefit of science and the welfare of his adopted country. The latest publication from his fertile pen which has reached us is that whose title stands at the head of this notice. Baron Mueller adopts the plan of describing in easy language several of the most prominent of the wild flowers of Victoria, beginning with the Gum trees (*Eucalyptus*), passing on to other members of the Myrtle family, such as the *Melaleucas* and *Eugénias*. Of these genera one or two species are taken as types, carefully but briefly described, their distinctive features contrasted, their place in the natural system indicated, their internal structure and useful properties pointed out. The *Wattles*, or *Acacias*, are similarly treated, then the *She Oaks*, or *Casuarinas*, and so on, through several natural orders, the author contriving to give in the short compass of 150 pages or so a general idea of the main features, so far as orders and leading genera go, of the flora of Victoria. Provided a little elementary knowledge of the parts of the flower be possessed to begin with, the little volume before us seems admirably adapted for the purpose for which it is intended. The woodcuts are numerous and characteristic, and, to our eyes, accustomed to European text-books, have the charm of freshness. With reference to the plan of the work, "an experience of nearly forty years has convinced the author that the use of a grammar-like publication for initiating into a study of plants is alike wearisome to the teacher and children, and that as a rule, subject to rare exceptions, the knowledge acquired from the ordinary first elementary works on botany is as quickly lost as gained. The only method of rendering such studies agreeable and lastingly fruitful consists in arousing an interest of the young scholars in the native plants of their locality, to afford them all possible facilities to recognise and discriminate all the various plants within reach, to lead them by observations thus started to comprehend the limits of specific forms of generic and ordinal groups, and to conduct them afterwards to the more difficult study of the special anatomy and physiology of plants."

We can endorse the Baron's opinion from our own experience. It is the huge mass of details and hard words that repel the beginner. If the subject be presented in a more attractive form, beginning with the simple and the common, and passing by degrees to the more complex and rare, greater progress and more lasting benefit is secured than by plunging at once into a lexicon of hard words and details whose significance and interdependence cannot be understood by the beginner. Moreover, to create an interest in structure and form their uses and adaptations must be explained. In fact, the habits and customs of plants require to be taught as well as their external forms, their resemblances and dissimilarities, and they add tenfold to the interest of the study.

Preventive Medicine and Public Health. By Dr. Alfred Carpenter. Simpkin, Marshall & Co.

Nothing is more characteristic of the medical practice of the present day than the advance of what the author calls preventive medicine. "Venienti occurrere morbo" has for ages been a medical axiom, and it was a good one all the time that the access of disease was considered to be a fatal necessity. Now-a-days, thanks especially to the doctors, it has been shown that in many cases disease is not a fell necessity, but that it is preventable if due precaution be taken. Instead of attacking the diseased body by pills and potions innumerable, the modern tendency is to place relatively little faith in physic. It

indeed has its uses—is sometimes a *sine quâ non*; it satisfies the patient, and still more eases the minds of sympathetic bystanders, naturally eager that "something should be done." But the doctors now know—subject of course to exceptions—that they have far more power to prevent than to cure disease; that is, when they are not thwarted by prejudice, ignorance, or self-interest. It is only necessary to look back to statistical records to show how the health of the population has steadily ameliorated of late years in this country. This lessened sickness and longer average duration of life have been the direct results of better drainage, sweeter homes, and greater attention to sanitary matters generally. In the little book before us Dr. Carpenter alludes to many of these points. He shows how prevention is better than cure; that cure, if it be possible at all by art, is clearly impossible if the natural history of disease is not fully known. Hence, our author touches lightly but suggestively on the mode of growth and propagation of fungi. He indicates the probability that many epidemic diseases are due to sudden waves of activity, if one may so speak, in certain germs, which, like the resting-spore of a fungus, may remain quiescent for a time till circumstances become propitious for their development.

Dr. Carpenter, it may be added, was one of the first to discover the resting-spore of the Potato fungus, though he did not follow up the subject, and at the time was scarcely, perhaps, aware of the importance of the discovery. Dr. Carpenter's views on sewage farms have been sharply contested. We do not intend to enter on the discussion of that subject now. It seems to us that, as usual, there is truth on both sides, and that a very great deal depends on the point of view of the respective controversialists. It is noteworthy, too, that Dr. Carpenter advocates a new theory of vegetable nutrition: plants according to him are not solely confined as to their diet to inorganic matter, but they can absorb and digest organic matter also. Dr. Carpenter's views of course receive support from the so-called carnivorous plants, as well as from the so-called "saprophytes," or plants that live on decaying animal matter. The root-hairs of Rye-grass have, according to Dr. Carpenter, the power of absorbing and digesting the organic matter of sewage. The facts as yet are not numerous enough to induce a physiologist to accept this view as proven, but at least it may be said that the tendency of the time is towards the belief that plant digestion is under certain circumstances essentially the same process as in animals, and in both cases connected with a process of fermentation or rapid change of constituents. Dr. Carpenter's book is rather loosely put together, and stands in need of some revision, but of its interest to the intelligent reader, apart from the medical students to whom it was originally addressed, there can be no question.

PUBLICATIONS RECEIVED.—Hamburger Garten Zeitung.—Bulletino della R. Società Toscana di Oriticultura.—The Forest and Chace of Malvern, with notices of the most remarkable old trees, by Edwin Lees.

Apiary.

THE CAPE, OR HOOD.—Our northern bee-keepers use many names which sound strange to the ears of people dwelling south of the Tweed, as, for example, the name we now are using would be called super by most apiarians. All well made straw bives should have a hole in the crown, about 2 inches in diameter; in the winter season this should be closed with a wooden plug, or, what is far better, with a bung. Directly the hive shows signs of being overcrowded—soon discovered by the bees clustering outside the entrance—the bung must be taken out, and the hood, or super, placed over the opening. The best form of super for cottagers is a small straw hood, made of lighter materials than an ordinary skep, as they are not intended for wintering purposes, but only as a temporary storage for the best honey of the season.

Our illustration, fig. 87, gives us a good form of cottage hood, in fact, we do not advise the use of square wooden boxes, for the simple reason we find the small straw supers when neatly filled with a well stored comb sell for a higher price than wooden boxes. It is far preferable to offer the super and comb entire for sale; never remove the comb, as it is often rendered unsaleable. A well stocked apiary should in good average honey years yield two or three

dozens of these small straw supers, each having 3 lb. of honey, and this without having fewer swarms or less hive honey the following autumn.

Just about the time when honey is the most abundant the greater part of the hive is filled with brood, under these circumstances the bees, not possessing any cells for honey storing, are compelled, although doubtless against their wishes, to be idle, thus they cluster like a huge bunch of Grapes at the entrance. Now, instead of this enforced idleness, if the straw hoods are given them in time, they make the best of them by working hard whilst the harvest lasts, for in our variable climate the honey yield lasts a very short time.

Our chief object in bringing before the notice of our readers the Scotch cape, or hood, at this season is to persuade the working apiarian to make a few straw supers during the long winter evenings; then when they are filled next year, to induce some of the

FIG. 87.—COTTAGE HOOD.

neighbouring tradesmen to exhibit them in their windows for sale, and, if their experience resembles ours, they will not wait long for customers. A.

Reports of Societies.

Royal Horticultural: October 2.—FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. The subjects exhibited to-day were more numerous, and certainly of a more interesting description, than those which appeared at the last meeting. By far the most valuable and most striking contribution was a magnificent group of Nepenthes from the nurseries of Messrs. James Veitch & Sons, and which was recommended to the Council for the award of a medal. This marvellously rich collection included large and remarkably fine examples of *Nepenthes Rafflesiana* × *N. Chelsoni*, a hybrid between *N. Hookeriana* and *N. Dominii*; the Bornean *N. Hookeri*, and a variety of the same named *elongata*, with longer and brighter coloured pitchers; and smaller specimens of *N. rubro-maculata*, a hybrid between an unnamed species and *N. hybrida*, to which a First-class Certificate was awarded. The pitchers are beautifully coloured at the mouth, and of medium size. × *N. Courtii*, a hybrid between a Bornean species and *N. Dominii*, with long club-shaped pitchers, to which a First-class Certificate was also awarded. *Nepenthes hybrida maculata elongata*, with long narrow pitchers, which gained a similar award. The parentage of this hybrid is the same as the last. *N. hybrida*, the result of a cross between *N. distillatoria* and *N. species*; *N. lirata* (× *N. hybrida* and *N. Rafflesiana*); *N. ampullaria vittata* from Singapore, *N. distillatoria* from Ceylon, *N. albo marginata* from Penang, *N. phyllamphora*, *N. Sedeni* (× *N. distillatoria* and *N. species*), *N. intermedia* (× *N. Rafflesiana* and *N. species*), *N. ampullaria* from Singapore, *N. Kennedyana* from North Australia, *N. zeylanica rubra* from Ceylon, &c. Fine examples of various *Sarracenia*s, such as *purpurea*, a highly coloured species from North America; *psittacina*, and *Chelsoni*, the latter a hybrid between *S. rubra* and *S. purpurea*; together with a most charming assortment of miniature examples of insectivorous plants. From the Chairman came cut flowers of *Escalonia pterocladon*, a fine white-flowered species that had been grown against a fence. A choice and beautiful collection of seedling *Gladioli* came from Messrs. Kelway & Son, who received a First-class Certificate for *G. Rhamnes*, a smooth and highly refined flower, scarlet in colour, with beautifully purple-pencilled lower petals. Messrs. Bell & Son, The Nursery, Norwich, sent several examples of *Adiantum Capillus-Veneris corymbiferum*, and a number of brightly coloured seedling *Begonia*s, obtained by crossing *Pearcei* and *grandiflora*. Messrs. William Paul & Son, Waltham Cross, received a vote of thanks for half-a-dozen boxes of cut Roses, an admirable display for the time of year; and including amongst others

especially fine blooms of *Souvenir de la Malmaison*, *Etienne Levat*, *Madame Clemence Joigneaux*, *Hippolyte Jamin*, *Saffrano*, *Charles Lefebvre*, and *Louis Van Houtte*, &c. Mr. Turner, Slough, made a most liberal contribution of cut blooms of bouquet *Dahlia*s, perpetual blooming *Carnations*, &c. The *Dahlia* blooms were shown in bunches set on a layer of moss, and, by reason of their exquisite forms and colours and great variety, were a source of great interest. To show the adaptability of these very showy flowers for indoor decoration, Mr. Turner exhibited a March stand, filled with blooms of these and sprays of Maidenhair Fern, which had a cheerful and pleasing appearance, and a vote of thanks was awarded, while the group received high commendation. The Tree *Carnations* were very brightly and freely bloomed, a new variety named *Osman Pacha*, in the style of *Scarlet Defiance*, but much darker in colour, was awarded a First-class Certificate. A similar award was also voted to Messrs. Rawlings Bros., Old Church, Romford, for *Dahlia*s Mrs. Willing and Mrs. Shirley Hibberd, the latter a pretty flower of a primrose ground, shaded and tipped with pink and rosy purple. Mr. Turner showed a few show *Dahlia*s, and Mr. Wheeler, Warminster, also sent a few new varieties. A small plant of the purple Norway Maple came from Messrs. Stewart & Sons, Dundee. A fine specimen of *Eryngium serra*, with its long deeply-serrated leaves, was contributed by Mr. Green, gr. to Sir George Macleay, Pendell Court, Bletchingley. A section of an old stem of *Heliotropium peruvianum* came from Lord Bridport's garden at Cricket, St. Thomas, Somerset. It grew for many years in the conservatory at that place, and so far back as 1837 covered 700 square feet of the back wall. From Burghley Mr. Gilbert sent several very fine seedling *Primulas*, and received First-class Certificates for *Princess*, bluish white, speckled and shaded with lilac; Mrs. Barron, a larger flower than the last, pink shaded and speckled with bright rose; and *White Lady*, a delicately pink-tinted white. They are all fine flowers, and a welcome addition to this charming class. Mr. Noble, Bagshot, again exhibited cut flowers of his new Rose, *Queen of Bedders*, which, as to its neat dwarf habit and wonderful freedom of bloom, proves to be all that its introducer claims for it. Sprays of *Libocedrus decurrens*, bearing numerous fruits, were sent by Mr. Miller, of Combe Abbey.

FRUIT COMMITTEE.—H. Webb, Esq., in the chair. This was a specially interesting meeting, and much more extensive than usual. Mr. Jones, The Royal Gardens, Frogmore, exhibited three magnificent fruits of the Smooth Cayenne Pine, weighing respectively 9 lb. and two of them 9½ lb. each, and the committee recommended them for the award of a Silver Banksian Medal. A handsome *Charlotte Rothschild* Pine, weighing 8 lb., and stated to be not eleven months old, came from Mr. Jones, Bentley Priory Gardens, Staomore; and Mr. Hutton, gr. to S. Swire, Esq., Crown House, Southport, sent two Providence Pines, weighing 8 lb. 12 oz. and 9 lb. respectively. Messrs. H. Lane & Son, Berkhamstead, sent a grand collection of Grapes, similar to others they have been showing this season, and the committee recommended the award of a Gilt Banksian Medal. Mr. Loney, gr. to George Dickson, Esq., Gothenburg, Sweden, sent a grand collection of Apples and Pears grown under glass, including twenty-three varieties of the former and seventeen of the latter. Amongst the Pears were very fine dishes of *Beurré Bachelier*, *Beurré Superfin*, *Duchesse d'Angoulême*, *Beurré d'Anjou*, *Beurré Dumont*, *Huyshe's Bergamot*, &c. The award of a Gold Medal was recommended. An interesting display of some three dozen varieties of Cob Nuts and Filberts came from the Society's garden, Chiswick; and from Mr. Bennett, Rabley, came a nicely coloured dish of Garibaldi Strawberries. Mr. Bennett also sent several fruits of his new seedling *Rabley Melon*, a pretty cross between Munro's Little Heath and Read's Scarlet-flesh, that promises well for market work, as it is said to possess the free-bearing qualities of the former, and the quality of the latter. It was not in condition to-day. Mr. Lewis Killick, Mount Pleasant, Maidstone, showed examples of *Stone's Apple*, a fine variety sent to the last meeting, and which now gained a First-class Certificate. G. F. Wilson, Esq., sent the *Early Ascot Frontinor* from a cold orchard-house, of very good flavour. Mr. Allen, The Gardens, Gunton Park, sent three *Royal Ascot Melons*, not in first-rate condition; and a new Melon, named *Cream Pine*, a long-ribbed, thick-fleshed, scarlet variety, from Messrs. James Carter & Co., was not ripe, but very promising. Mr. Gilbert, Burghley, sent a dish of very fine Brussels Sprouts, and two splendidly grown bunches of *Gros Colman Grapes*, which were recommended for a bronze medal. Mr. Gilbert's variety of this Grape is no different to any other *Gros Colman*, but he has certainly grown it better this season than any we have seen yet. Messrs. Lane & Son had it very fine, but not like the Burghley sample. It requires very severe thinning. Mr. Turner sent

nice dishes of Early Bird, a handsome looking kidney Potato, White Wonder and Duneden, round and flattish round varieties. Mr. Allen, Gunton Park, sent examples of Williams' Magnum Bonum, and a seedling globular shaped Onion. Messrs. Kelway & Son, Langport, sent specimens of eighteen varieties of Cucumbers, many of them yellow, and all of them too large for useful table work. Mr. Harrison Weir, Weirleigh, Brenchly, showed some fine samples of Venn's Black Muscat and Muscat Champion Grapes, grown without any fire-heat, and the award of a small Silver Banksian Medal was recommended. To Mr. Shirley Hibberd the honour is due of having introduced something new in cultivation to the notice of the committee in the form of an admirable illustration of his system of cultivating Watercresses in pans, and which has already been described in our columns at p. 616, vol. iv. The varieties shown to-day were the well-known Springhead Brown Cress, the Stoke Newington Purple Cress, a free growing local variety with somewhat larger leaves than the Brown Cress, and, best of all, the Erfurt Sweet Cress, which Mr. Hibberd describes as the most tender and delicately flavoured variety. Mr. Hibberd's plan is to plant his cuttings in pans filled with loam, placed about 1 inch deep in water in another pan, and kept well watered. The first cutting will be ready in about six weeks, after which the process is "cut and come again" until they become exhausted, when a fresh plantation is made. By this means a supply can be kept up all through the summer by any one who will take the trouble to acquire it; and even all through the winter, by those who can give them the protection of glass. The award of a bronze medal to Mr. Hibberd was recommended by the committee. Messrs. James Carter & Co. contributed a particularly interesting assortment of Capsicums, which included several curious varieties which we had not previously seen. There were the scarlet and yellow Tomato-shaped varieties; the Sweet Spanish, the red and yellow square varieties, the large bell or bull's-nose form, the Sweet Mountain Purple, and the New Giant Emperor, an immense scarlet variety of an angular form, and of the size of a well-grown Early Nantes Horn Carrot. A large collection of Potatos came from Mr. Turner, which no doubt we shall see again at the Aquarium; and from Mr. Hepper, gr. to C. O. Ledward, Esq., The Elms, Acton, came a good dish of Tomatos. Last, but not least in its importance, we have to include in this notice a very considerable display of Apples made by Messrs. William Paul & Son, of Waltham Cross.

The International Potato Show: Oct. 3, 4, and 5.—In the exhibition which opened at the Royal Aquarium, Westminster, on Wednesday last, and closed last night, we had for the first time something like an international show, inasmuch as it included at least one foreign collection, and we had besides such a magnificent show of noble tubers as certainly has never been seen before. We do not mean to say that the preceding exhibitions of the kind were not larger, but for genuine quality this one proved a long step in advance of its predecessors, and the managers must certainly be complimented on the success which is attending their endeavours so far to improve the form of this valuable root, and as a consequence its culture also. When the first exhibition was held, at least three-fourths of the samples shown were of the old-fashioned deep-eyed type, rendered even more worthless by reason of their increased size; and it is a remarkable fact that, judged by what is exhibited only after a lapse of a few years in an exhibition of somewhat similar dimensions, the ugly wasteful roots have almost been swept into the limbo of obscurity. The prizes, as on previous occasions, were awarded by men who know the value of quality as distinguished from mere size, and the awards undoubtedly went to the best. The foreign collection previously alluded to was sent by Messrs. B. K. Bliss & Sons, of New York, perhaps the most extensive exporters of new varieties in the States; but we are constrained to say that if the samples sent are to be taken as the reflex of what obtains in America, our friends are a long way behind in their notions as judged by our standard. Their own pet varieties were numerous shown here in far better form and condition than they were exhibited by themselves—a circumstance of which our growers may well feel proud.

The luncheon in the afternoon was well attended by judges, members of the committee, and friends of the movement, and amongst much that could only be considered as "chaff" in the subsequent speeches there was enough of good corn to convince any one that the promoters of the exhibition are doing a good and most praiseworthy work. Replying to the toast of "The Visitors," Mr. Henry Vilmorin, of Paris, threw out the suggestion that a representative collection of Potatos should be sent to the Paris Exhibition next year, and the idea seems to us such an excellent one that we would fain hope it will be carried out, and under the management of the same committee, who could no doubt obtain the permission of exhibitors

to impound the finest samples of each representative kind for so worthy an object.

The premier class was that for twenty-four distinct varieties, nine tubers of each, and there were no less than fifteen competitors. In all respects this class included a remarkable lot of Potatos, most of the samples being of fair size, very clean, and evenly grown. All the prizes in this class were given by the Royal Aquarium Company, and the 1st, the handsome sum of twelve guineas, was won by Mr. Peter McKinlay, Woodbine Cottage, Beckenham, who had exceedingly fine examples of Climax, rough skinned white round; King of Potatos, white pebble-shaped; Onwards, and Porter's Excelsior, white rounds; Brownell's Superior, red kidney; Breadfruit, white kidney; Purple Ashleaf, kidney; Early King, white pebble-shaped; International, white kidney; Early Rose, McKinlay's Pride, a handsome new white kidney; Gramplan, red round; Schoolmaster, and Model, white rounds; Salmon Kidney, Rector of Woodstock, and Taylor's Seedling, white rounds; Blanchard, mottled round; Garibaldi, red kidney; Alexandra, white kidney; Late Rose, Snowflake, Emperor, red rounds; and the Ashton Fluke. The 2d prize was taken by Mr. Finlay, gr. to Colonel North, Wroxton Abbey, Banbury, with a grand lot, including beautiful examples of the International, Salmon, Perfection, Myatt's Prolific, Snowflake, Magnum Bonum, Bresee's Prolific, and Edgcott Seedling, kidneys; White Emperor, Porter's Excelsior, Climax, and Schoolmaster, white rounds; Blanchard and Princess of Lorne, mottled rounds; and Walnut Kidney, Scotch Blue, &c. Mr. James Pink, gr. to Lord Sondes, Faversham, was placed 3d, with a capital lot, including many of the sorts above named and Waterloo Kidney, the Hundredfold Fluke, the Birmingham Pritzetaker, Giant King, white round; Coldstream, Early Goodrich, and Ruby. Mr. William Ironside, Mains of Keith Hall, Inverurie, N.B., came in 4th, and Mr. R. Dean, Ealing, 5th; and a collection from Mr. Farquhar, of Fyvie, was highly commended, while commendations were bestowed upon collections from Mr. Turner, Slough, and Mr. Thomas Pickworth, of Loughborough, Leicestershire.

In the class for eighteen varieties, distinct, nine tubers of each, there were seventeen competitors, and, with one exception, their productions were of a very good and uniform quality, none being over large, but generally clean, smooth, and attractive in appearance. The 1st prize, a silver cup, value £10 10s., given by Messrs. Sutton & Sons, Reading, was won in capital style by Mr. William Porter, King Street, Old Meldrum, who put up remarkably handsome samples of Penn's Bountiful, red kidney; Improved Ashton Fluke, white kidney; Crimson Walnut-leaf, red kidney; International, white kidney; Napoleon, white kidney; Bresee's Prolific, white round; Blue Prince, blue round; Model, white pebble-shaped; Early Emperor, red round; Snowflake, white kidney; Porter's Excelsior, white round; Blanchard, mottled round; Albion Kidney, white; Blue Ashleaf, blue kidney; Climax, white round; Meldrum Conqueror, white kidney; Gramplan, red round; and Rector of Woodstock, white round. The 2d prize, of six guineas, given by Mr. John Courts, King Street, Covent Garden, also went to an Aberdeenshire grower, Mr. George Donaldson, of Inverurie, who staged admirable examples of Lye's Favourite, white round; Schoolmaster, white pebble-shaped; Purple Ashleaf Kidney, Webb's Imperial, white kidney; Early Handsworth, white round; Napoleon, red kidney; Turner's Union, white pebble-shaped; Carter's Main Crop, mottled round; Yorkshire Hero, white kidney; Gramplan, Dalmahy, white round; and Scotch Blue, blue round. Mr. James Crute's 3d prize went to Mr. G. B. Syley, Sycroton Lodge, Newark, who had a particularly clean and well grown lot, including amongst others very superior samples of Mona's Pride, Snowflake, Waterloo and International, white kidneys; Garibaldi and Early Vermont, red kidneys; and Early Don, Bresee's Peerless, and Early Market, white rounds; and a dish of Scotch Blue, blacker in colour than any that has come under our notice before. Mr. James Pink, gr. to Lord Sondes, Faversham, Kent, was 4th, with medium sized samples full of quality.

Seventeen exhibitors competed with a dozen dishes each, and the class included a great number of very superior samples, but as a whole they lacked the uniformity in quality which was so distinguishable a feature in the preceding classes. The whole of the prizes in this class were given by Messrs. James Carter & Co., of High Holborn, and the 1st, of six guineas, was taken by Mr. James Pink, who had medium-sized but cleanly and evenly grown specimens of Schoolmaster, Birmingham Pritzetaker, Red Emperor, Coldstream, Early Rose, Bresee's Prolific, Early Goodrich, Ruby, Waterloo Kidney, Snowflake, Garibaldi, and Berkshire Kidney. Mr. Charles Ross, gr. to C. Eyre, Esq., Welford Park, Newbury, was a good 2d, Mr. William Finlay a good 3d, and Mr. Cornfoot, close up, 4th.

Class D, was for nine varieties; there were eighteen competitors, and the remarks we made upon the last

class apply with equal force to this, which included an even greater number of coarse samples, though these were not many in number. The 1st prize of five guineas, given by the Lawson Seed and Nursery Company, Edinburgh, was won by Mr. R. Dean, Ealing, with splendid examples of King of Potatos, Purple Ashleaf, Extra Early Vermont, International Kidney, Excelsior Kidney, Gramplan, Climax, Blanchard, and Salmon Kidney. Mr. Peter McKinlay was a remarkably good 2d with handsome samples of Select Round Blue, Snowflake, Crimson Walnut-leaf, Alexandra Kidney, Blanchard, King of Potatos, Model, Ruby, and McKinlay's Pride. Mr. William Ellington, Mildenhall, Soham, was 3d; and Messrs. Lott & Hart, Whitehill Nursery, Faversham, 4th.

In the six dishes class the competition was unusually strong, no less than twenty-three exhibitors competing. A remarkably good class it was too. Another silver cup, value five guineas, given by Messrs. Daniels Brothers, Norwich, was won by Mr. William Finlay, who put up Blanchard, Edgcott Seedling, Scotch Blue, Snowflake, Magnum Bonum, and Walnut Kidney, all of excellent table size and undeniable quality; 2d, Mr. W. Ellington, Mildenhall; 3d, Mr. W. Ironside, Inverurie; 4th, Mr. James Miller; and, highly commended, Mr. H. Minchin, The Nurseries, Hook Norton; commended, Mr. Gilbert, Burghley; Mr. James Pink, Mr. F. Jones, Boughton House, Kettering; and Mr. C. Osman, Sutton.

The class for four dishes was also a remarkably good one, and Mr. F. Miller, gr. to J. F. Friend, Esq., Margate, took Messrs. J. C. Wheeler & Son's prize, with large and very clean samples of Ashton Fluke, Breadfruit, Blanchard, and Snowflake. The other awards went to Mr. J. Denyer, Penge Road, Beckenham; Mr. G. Donaldson, and Messrs. Lott & Hart. There were twenty-three lots.

Four dishes each of distinct new varieties not in commerce were shown by several exhibitors, and the awards went, in the following order—to Mr. James Pink, with Covent Garden Perfection, white kidney; Superior, a handsome red American kidney; Handsworth Superior, also a white kidney; and a red seedling round with white eyes. Mr. R. Dean, with Garibaldi, a red kidney; Bedford Prolific and International, white kidneys; and Radstock Beauty, a mottled round. Messrs. Lott & Hart, with Success, Centennial, red round; Lye's Favourite, and Prince Arthur. Mr. R. Farquhar, with Heather Bell, mottled kidney; Centennial Ice Cream, a handsome white kidney; and Sims' Telescope, a long, thin, red kidney. With two distinct varieties, one round and one kidney, Mr. R. Dean came in 1st, with Schoolmaster and International Kidney; 2d, Mr. F. Miller, with Schoolmaster and Jackson's Favourite Kidney; and 3d, Mr. C. W. Howard, Canterbury, with Magnum Bonum Kidney and Climax. A wonderfully beautiful dish of Rector of Woodstock, shown by Mr. R. Ironside, Ingliston, Inverurie, was 1st in the class for a single dish of any white round variety; and in the corresponding class for coloured rounds, Mr. James Pink took the lead with Red Emperor. Yorkshire Hero, shown by Mr. F. Miller, proved to be the best single dish of white kidneys; and Superior, shown by Mr. J. S. Evenden, Longfield, Dartford, the best coloured variety. The finest dish of Snowflakes came from Mr. Pink; of Ruby, from Mr. C. Ross; of Porter's Excelsior, from Mr. Pink; and of Schoolmaster, from Mr. J. Hall, Gillingham, Kent.

The committee last year adopted the practice of giving Certificates of Merit to seedling Potatos, taking as the basis of their award a clean, handsome shape and distinct appearance. It is done to stimulate raisers, at the same time the question of quality for table purposes is one that cannot be determined. It must be left to cultivators to discover that.

On this occasion First-class Certificates were awarded McKinlay's Pride, a very handsome early white kidney of great promise, shown by Mr. P. McKinlay; to Radstock Beauty, a very handsome round variety in the way of Lye's Favourite, but quite distinct from it, a second early variety, shown by Mr. Richard Dean; to Vicar of Laleham, a seedling from Emperor and Victoria, having the form of the latter with a purple skin and white flesh—really a purple Victoria, raised by the Rev. Mr. Peake; to Bedford Prolific, an improved Onwards, an early white variety of good quality and a rare cropper, from Mr. R. Dean; to White Emperor, a very handsome white counterpart of this well-known variety, shown by Mr. Henry Minchin; to Early Bird (Boutell), an early white kidney, and very handsome, but not a seedling, being a good selection only from Veitch's Improved Ashleaf, shown by Mr. Charles Turner; to Ice Cream, a very handsome pale yellow early kidney, quite distinct in appearance, shown by Mr. R. Farquhar, Fyvie Castle Gardens; and to Trophy, an American variety, shown by Messrs. B. K. Bliss & Sons, New York—to all appearance a red Snowflake, and likely to be as useful as that popular variety. There were many new varieties, but the foregoing were regarded as the most distinct and promising. Messrs. Sutton & Sons, Reading, had a large lot of Magnum Bonum, which has this season proved an

excellent main crop Potato, and it was highly commended by the judges.

There were also large and varied collections of Potatoes from Messrs. Carter & Co., Holborn; Messrs. Daniels Bros., Norwich; Mr. W. Porter, Old Meldrum; and Mr. C. Turner, Slough; all of which were highly commended.

Sept. 27.—Dull, with dense fog till 11 A.M. Fine and clear till 4 P.M. Cloudy till 7 P.M.; cloudless at night.
 — 28.—A fine day, generally cloudy. Fog in morning and evening. Cloudless at night.
 — 29.—A very fine day, cloudy till 11 A.M. Fog in morning. Cloudless at night.
 — 30.—A fine, bright, clear day. A little mist in morning. Cloudless at night.
 Oct. 1.—A fine day, partially cloudy.
 — 2.—Very fine and clear throughout. Fog and mist till 10 A.M. Cloudless at night.
 — 3.—A fine day, partially cloudy. Very cold. Foggy in morning.

LONDON: *Barometer*.—During the week ending Saturday, September 29, in the suburbs of London the reading of the barometer at the level of the sea decreased from 29.97 inches at the beginning of the week to 29.92 inches by the morning of the 23d, increased to 30.25 inches by the morning of the 25th, decreased to 30.20 inches by the afternoon of the same day, increased to 30.41 inches by the morning of the 27th, and decreased to 30.21 inches by the end of the week. The mean reading for the week at sea level was 30.21 inches, being 0.14 inch above that of the preceding week, and 0.28 inch above the average.

Temperature.—The highest temperatures of the air observed by day varied from 61.5° on the 29th to 54.3° on the 25th; the mean value for the week was 60°. The lowest temperatures of the air ranged from 35° on the 25th to 44.1° on the 23d and 26th; the mean for the week was 41.1°. The mean daily range of temperature in the week was 18.3°, the greatest range in the day being 23.1°, on the 29th, and the least 11°, on the 23d.

The mean daily temperatures of the air were as follows:—23d, 49.7; 24th, 50.6; 25th, 44.1; 26th, 51.3; 27th, 48.1; 28th, 48.7; 29th, 50.2; and the departures in defect of their respective averages were 5.5, 4.4, 10.7, 3.4, 6.5, 5.8, 4.2. The mean temperature of the air for the week was 49°, being 5.8 below the average of sixty years.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 124° on the 29th, 110° on the 27th, 109.5° on the 24th, and 101° on the 26th; on the 25th the reading did not rise above 72.5°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 25.1° on the 25th, 28.1° on the 29th, and 30° on the 28th. The mean of the seven low readings was 33.5°.

Wind.—The direction of the wind was N., N.E., and N.W., and its strength gentle. The weather during the week was generally fine and dry but cold. Fog prevailed on the 27th, 28th, and 29th.

Rain fell on two days during the week; the amount measured was 0.05 inch.

ENGLAND: *Temperature*.—The highest temperatures of the air observed by day were 66° at both Truro and Eccles, 65.3° at Cambridge, 65.3° at both Leicester and Nottingham, and 65.1° at Blackheath; the highest temperature at Portsmouth, Wolverhampton, and Leeds was 59.1°; the mean value from all stations was 62.1°. The lowest temperatures of the

air observed by night were 31° at Cambridge, 33° at Hull, 33.1° at Nottingham, and 35° at both Blackheath and Sheffield; the lowest temperature at Liverpool was 45.1°, and at Sunderland 44°; the general mean from all stations was 37.1°. The range of temperature in the week was the greatest at Cambridge, 34.3°, and the least at Portsmouth, 16.1°; the mean range from all stations was 25°.

The mean of the seven high day temperatures was the highest at Truro, 63.1°, and Bristol, 61.1°, and the lowest at Bradford, 55.1°; the mean value from all stations was 58.1°. The mean of the seven low night temperatures was the lowest at Cambridge and Nottingham, both 38.1°, and the highest at Portsmouth, 48.1°; the general mean from all stations was 42.1°. The mean daily range of temperature in the week was the greatest at Bristol, 22°, and the least at Liverpool, 10°; the mean daily range from all stations was 16.1°.

The mean temperature of the air for the week from all stations was 49.1°, being 5.1° lower than the value for the corresponding week in 1876. The highest was 53°, at Truro, and the lowest 47°, at Wolverhampton and Hull.

Rain.—Scarcely any rain fell during the week. At Norwich 0.20 inch fell, at Sunderland 0.15 inch fell, at Brighton, Portsmouth, Plymouth, Truro, Wolverhampton, and Leeds no rain was measured; the average fall over the country was 0.04 inch only.

The weather during the week was generally fine, dry, and cold. Fog was prevalent at most places on the 27th, 28th, and 29th inst.

SCOTLAND: *Temperature*.—The highest temperatures of the air observed by day varied from 66° at Dundee to 60° at Leith; the mean value from all stations was 62.1°. The lowest temperatures of the air observed by night ranged from 34° at Paisley to 42° at Greenock; the mean value from all stations was 38.1°. The mean range of temperature from all stations was 23.1°.

The mean temperature of the air for the week from all stations was 51.1°, being 3° lower than the value for the corresponding week in 1876. The highest was 53°, at Glasgow, and the lowest 50.1°, at Paisley.

Rain.—The amount of rain measured at Aberdeen was 0.15 inch, at Edinburgh was 0.05 inch, and at Leith and Perth 0.03 inch. At Glasgow, Dundee, Greenock, and Paisley no rain was measured. The average fall over the country was 0.03 inch.

DUBLIN.—The highest temperature of the air was 67°, the lowest 33.1°, the range was 33.9°, and the mean was 51.1°. No rain fell.

REMARKS ON THE WEATHER DURING SEPTEMBER.—The mean reading of the barometer for the month was 29.88 inches, being 0.08 inch above the average of the preceding thirty-six years. The range of readings in the month amounted to 0.73 inch.

The maximum temperature of the air was 71°.6 on the 11th, and there are only two instances of so low a maximum back to 1841.

The minimum temperature of the air was 35°, being lower than any value since 1872.

The mean high day temperature of the air for the month was 62°.5, being 5°.2 below the average of the preceding thirty-six Septembers.

The mean low night temperature of the air for the month was 46°.4, being 2°.8 below the average of the preceding thirty-six Septembers.

The mean temperature of the air for the month was 53°.3, being 3°.3 and 4° lower than the averages of the preceding 106 years and thirty-six years respectively. About 1771 there are but six instances of so low a mean temperature for the month of September, viz.:—In 1771 it was 52°, in 1786 it was 51°.3, in 1793 it was 52°.8, in 1803 it was 52°.4, in 1807 it was 53°.1, and in 1829 it was 53°.2.

The mean temperature of the dew-point for the month was 47°.1.

The mean amount of cloud for the month was 6.2.

Rain fell on ten days, being two days less than the average number for September. The amount collected was 1.23 inch, being 1.20 inch below the average of the preceding sixty-two years.

The weather during the month was dull, cold, and dry. The month was remarkable for its low temperature and deficiency of rainfall. Fog prevailed on the 16th, 20th, 27th, 28th, and 29th.

JAMES GLAISHER.

Variorum.

"ETHNOLOGICAL HINTS AFFORDED BY THE STIMULANTS OF THE ANCIENT AND MODERN SAVAGES" (by Miss A. W. Buckland).—The study of primitive agriculture, which formed the subject of the memoir read by the author before the British Association last year, led naturally to that of the stimulants adopted by different races, because it was found that from a very early period in the history of mankind some sort of stimulant had been used almost univers-

ally. Among the lowest races this consisted now, as in ages past, only of some root or leaf chewed for its strengthening and invigorating properties, such as the Pitberry, recently discovered in use among nations in Central Australia, and the Cocoa leaf among the Indians of South America; but no sooner did the nations advance to the agricultural stage than they began to make fermented drinks from the roots or grains cultivated for food. Hence the beer of Egypt, which probably found its way with the Wheat and Barley of that land to the Swiss lake dwellings and over a great part of Europe, having been evidently known in Greece and Rome at a very early period, whilst a similar liquor still formed the chief beverage of all African nations, being now, as formerly in Egypt, fermented by means of plants. In China and Japan Rice was and is used to make wine or beer instead of Wheat or Barley or American Maize. In Bolivia this is chewed to produce fermentation, like the "kava" of the South Sea Islands—a practice which reappears among the inhabitants of Formosa, who use Rice instead of Maize. The sour milk or "koumis" of the pastoral tribes of Central Asia, and the mead of the ancient Scandinavians, both reappear among the Kaffirs of South Africa. Palm wine was used wherever Palms flourished, but wine of the juice of the Grape, although known in very ancient times, seemed to have been confined to the civilised races of Western Asia and Egypt, extending later to Greece and Rome. The multitude of wines described by Pliny were, however, in almost all cases flavoured with herbs or garden plants for medicinal purposes. The conclusions to be drawn from the history of fermented beverages, as recorded by travellers, were that the earliest stimulants were simply leaves and roots chosen by animal instinct, chewed, and found by experience to produce exhilaration and strength. With the dawn of civilisation, these roots and plants, still chewed, were mixed with water, and thus a kind of fermentation was induced, producing a mildly intoxicating drink, and when the agricultural stage was attained the cereals took the place of the earlier roots and leaves, and were also probably at first chewed to produce fermentation, as still in Formosa and South America, to be superseded in a higher degree of civilisation with the use of the Grape; yet even in this, as in the liquors made from grain, the roots and plants of an earlier age were retained for flavour, and to produce fermentation; and even the form and material of the earlier drinking cups were retained in civilised countries skilled in the manufacture, whilst the originally medicinal character of these beverages gave rise to many superstitions, to the deification of plants, and their dedication to various gods—to the birth of gods of wine, as well as to the universal custom of commencing every orgie with libations to the gods, and of proposing healths at feasts. The art of distillation, though probably known early in the Christian era, is comparatively modern, and was certainly unknown to savage races until "fire-water" was introduced, to their serious detriment, by Europeans.

IVY EMBROIDERY.—It has not yet occurred to the masters of decorative gardening that the Ivies are capable of furnishing most valuable material for certain kinds of embroidery planting, which probably would tell with best effect in a large garden wherein spring flowers play an important part in the annual colouring. There are not many varieties adapted to such work, but the few that are evidently best fitted for it are conspicuously appropriate. Thus amongst the climbers we have *marginata grandis*, which would probably be the best for forming bands of silver, and there are several others of the same section available where a weaker growth would be required, and in some soils the pretty *marginata rubra* would develop a fine tone of red in the winter. For yellow leafage there is no climbing variety good enough, but the well-known tree Ivy named *areum* produces a brilliant growth of orange-coloured leafage, and in a poor soil is very constant. The little minima is distinctly purple in winter, and Hibberd's Emerald would be the most useful of the green class, as it is a better colour during winter than the Irish Ivy, which is both too dark and too coarse for the purpose, and from March to August it presents a rich and dense growth of golden green leafage. Others would come in of course, as *nigra* for a very dark green, and *lucida* for glossy bronze, tortuous for a neat growth of very dark, highly-polished leaves. In any case, the surest to begin with are *marginata grandis*, *areum*, and *Emerald*. With these to form the more distinctive outline, it would be no difficult matter to fill up with a selection of a dozen or so of the neat growers with both green and variegated leaves, because for certain parts of a pattern the silver tree Ivies would come in well. A garden boldly framed in Ivy embroidery would have a charming appearance all the winter, and if a good assortment of spring flowers appeared amongst the Ivies from March to May, the Ivies would afford in their interest a strong, definite, and rich foundation, or setting, and quite a new and characteristic style of gardening would result. As this is a note of "observation," as well as of

SIR J. PAXTON'S HOTHOUSES for the MILLION.—Price List free. Conservatories, &c., built to Architects' Plans, or Designs prepared and Estimates given to Rough Sketches, with sizes required. Heating apparatus fixed complete. Pamphlet, with Illustrations, post-free, 3d.
HEREMAN AND MORTON, 2, Gloucester Street, Regent's Park, London, N.W.

Greenhouses.

H. FREEMAN AND SONS, HORTICULTURAL BUILDERS and HOT-WATER APPARATUS MANUFACTURERS, Cambridge Heath Bridge, Hackney, E. Good substantial made GREENHOUSES, Glazed, ready for fixing, 42 feet long, 12 feet wide, £50; 21 feet by 13 feet, £28; 12½ feet by 10 feet, £15. Estimates given in wood or iron.

Metallic Hothouse Builder to Her Majesty.

HENRY HOPE (late Clark & Hope, formerly Clark),
HOTHOUSE BUILDER and HOT-WATER APPARATUS ENGINEER.
 55, Lionel Street, Birmingham. Established A.D. 1818.
 BOOKS OF DESIGNS, 5s. each.
 The Extensive Ranges of Metallic Hothouses in the Royal Gardens, Windsor and Osborne, were executed in this Establishment.

SHAW'S TIFFANY, ELASTIC NETTING, CANVAS, &c., for Shading, Protecting, and other Horticultural Purposes. For Samples and Prices apply to **JOHN SHAW AND CO.**, 29, Oxford Street, Manchester.
 Established over a Quarter of a Century.

Is in use over many thousand miles, and has been awarded the Medals and highest Commendation of all the leading Agricultural Societies.
 It is constructed with **POWERFUL WINDING STRAINING PILLARS, RIGID INTERMEDIATE IRON POSTS, STRONG and DURABLE WIRE CABLE STRANDS,** forming the most efficient Strained Iron Fencing known for agricultural and general purposes.

Continuous Bar Iron Fencing.

With bars secured by F. M. & Co.'s Patent Self-locking Joints, which effectually prevent the uprights being pushed aside, and are independent of loose pins, wedges, or staples.

IRON ENTRANCE and FIELD GATES, IN WROUGHT AND CAST IRON,

Designed for the Mansion, Villa, or Farm, **WICKET AND GARDEN GATES,** In Great Variety of Patterns.

Iron Hurdles, Railing, Tree Guards, FRUIT ESPALIERS, WALL FRUIT TRAINERS, &c.
 Illustrated and Described in F. M. & Co.'s New Catalogue, sent on application.

IMPROVED LIGHTNING CONDUCTORS, With fittings complete, simple in construction, and easily erected by a careful mechanic.

Pit Lights and Sills or Brick Walls or Earth Banks.

PIT LIGHTS and FRAMES complete for fixing on Brick-work, made in two sizes of Lights to work 6ft. by 4ft. 2 in. thick, 7ft. 6in. by 4ft. 2½ in. thick, Lights glazed with 21 oz. British sheet glass, painted four times, sills 4½ in. by 3 in., with bearers and parting pieces complete, with screws, wrought-iron handle to each light, and strengthening bar across.
 Cash Prices. Carriage paid to any Railway Station in England and Wales; also to Edinburgh, Glasgow, Dublin, Belfast, or Cork.
SILLS or FRAMES, with 2 Lights, 6ft. by 4ft., 8ft. long by 6ft. wide, £2 16s.; 3 Lights, 6ft. by 4ft., 12ft. long by 6ft. wide, £4 3s.; 4 Lights, 6ft. by 4ft., 16ft. long by 6ft. wide, £5 10s.; 2 Lights, 7ft. 6in. by 4ft., 8ft. long by 7ft. 6in. wide, £3 10s.; 3 Lights, 7ft. 6in. by 4ft., 12ft. long by 7ft. 6in. wide, £5 2s.; 4 Lights, 7ft. 6in. by 4ft., 16ft. long by 7ft. 6in. wide, £6 14s. Prices for longer lengths at cheap rates. Prices on application.
 Catalogue of every description of Horticultural Building, post-free, 24 stamps. Plant Preserver Lists, Melon Frame Lists and Greenhouse Lists, post-free.

AGRICULTURAL LOCOMOTIVES, STEAM PLOUGHING MACHINERY, ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES, STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,

AVELING & PORTER, ROCHESTER, KENT; 72, CANNON ST., LONDON, E.C.; and 9, AVENUE MONTAIGNE, PARIS.

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their ro-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power, with a consumption of three and one-fifth pounds of coal per horse-power per hour.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes:—

Sizes.		To heat of 4-in. Pipe		Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 "	18 "	300	7 0 0
20 "	18 "	24 "	400	8 0 0
22 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	30 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
24 "	24 "	42 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Batham Hill, S.W., May 29, 1873.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS of HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.

When ordering Boilers please refer to the above advertisement.

STEVENS' TRENTHAM GREENHOUSE BOILER, After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved.

Copy of a Testimonial.

"Messrs. SILVESTER, Royal Exotic Nursery, King's Road, Chelsea, S.W.—Aug. 8, 1877.

"GENTLEMEN.—In reply to your enquiry as to our opinion of your Stevens' Treatham Boilers, we do not hesitate to pronounce them to be by far the best Boilers we have ever used. Our establishment is a very large one, and we have tested most of the various descriptions of Boilers which have been brought out from time to time. We originally commenced with one Treatham Boiler, and we have now thirteen of various sizes at work.

"For certainty of action, economy in fuel, and freedom from breakdown, we have never had a Boiler at all equal to the Stevens' Riveted Treatham Boilers supplied by you, and we have never felt so little anxiety in connection with our hothouses during the cold winter months as we do now.

"We are not in the habit of giving testimonials, but we think this may fairly be an exception to our rule, as the matter is one of such importance to the Gardening Public generally, and our experience has led us to form a very decided opinion.

"We are, Gentlemen, yours faithfully,
"JAMES VEITCH AND SONS."

For Illustrations, with full particulars, apply to the Sole Makers,
F. & J. SILVESTER,

HOT-WATER ENGINEERS, &c., &c.
 Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

KINAHAN'S LL WHISKY.

Universally recommended by the Medical Profession, A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.
DINNEFORD AND CO.,
 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S PILLS.—Nervous Debility.—Persons who feel weak, low, and nervous may rest assured some serious ailment is looming in the distance, against which instant action should be taken. Holloway's Pills present the ready means of exciting energetic action on the Liver, liberating accumulated bile, and lifting at once a load from the spirits and expelling a poison from the body. This simple and natural method of remedying the first tendency to disease gives present ease and ensures future safety. The Pills, and all those who are Losing Flesh, should try these Pills, which are especially useful when the Digestive or other functions are imperfectly performed and demand immediate correction, or in after years neither mind nor body will be well developed.

Send for a PRICE LIST of

BLAKE'S SELF-ACTING HYDRAULIC RAMS,

For Raising Water for the Supply of Villages, Irrigation, Railway Stations, Mansions, Fountains, Farms.

No Cost for Motive Power, which is obtained from the Stream of Water passing through the Rams.

NO OILING OR PACKING REQUIRED.

Made in sizes to raise from 300 to 100,000 Gallons per day.

WILL FORCE TO A HEIGHT OF 1,500 FEET.

This advertisement will appear again in three weeks.

This Ram will raise a part of the same water that works it, or will raise pure water from a well whilst it is worked by a stream of impure water.

TESTIMONIALS.

From the Right Hon. T. SOTHERN ESTCOURT, *Estcourt Park, Gloucestershire, September 6, 1875.*

"You will be glad to hear, as I am to tell you, that your Self-acting Hydraulic Ram has worked exceedingly well and continuously since it was erected, more than twelve months ago. It is, in fact, perfectly successful."

(The delivery pipe in the above case is 4200 feet long, with 100 feet rise.)

From Captain TOWNSHEND, *Wimham, February 10, 1877.*

"In answer to your inquiry, I am glad to say the Hydraulic Ram you sent me in November, 1875, is working exceedingly well, and gives no trouble. It will work when quite immersed, as it has been several times during the floods this winter, forcing up water through a delivery pipe 900 yards long at the rate of 80,000 gallons per day, although you only promised 50,000."

From JOHN BARNES, Esq., *Contractor, Chetburn and Helthfield Railway, Contractor's Office, March, 1877.*

"Dear Sir,—I have the pleasure to inform you that the three Hydraulic Rams you erected for me on this contract about two years ago, have continued to work very satisfactorily, without requiring any repairing. With a fall of 5 feet sufficient water has been raised daily by each Ram to supply two of my locomotive engines: they have fully answered my expectations and all that has been said of them."

Deanwater, Wilmslow, November 20, 1875.

"Dear Sir,—In answer to your inquiries respecting the Hydraulic Ram you supplied me with six months ago, I beg to state that I am more than satisfied with it, as it is in perfect order, sending up to the top of the house about 2000 gallons of water in the twenty-four hours, whereas you only contracted to deliver in that time 500 gallons. I have, therefore, every reason to be well pleased with your work, and more especially as I had a Ram supplied me by another maker which could not send up a single gallon of water to the height required, and a second maker informed me that no Ram with a fall of 5 feet could send up water to the distance required, namely, 120 feet. But yours is an accomplished fact, and does its work most effectually.—I am, yours truly, L. HANMER."

From Mr. THOMAS MASON, *Alkinoates Hall, Colne, September 30, 1871.*

"Sir,—Your self-acting Hydraulic Ram gives me entire satisfaction; it has been at work about fifteen months, and has only been seen once during the last six months; it is forcing about 1400 gallons per day of twenty-four hours to a height of 104 feet."

From JOHN PENNINGTON, Esq., *Emmott Hall, near Colne, December 21, 1868.*

"Sir,—The Self-acting Hydraulic Ram you supplied me with nine months ago continues in excellent condition. It receives water from a spring through a 2-inch pipe, of which it forces 3600 gallons per day of twenty-four hours to a height of 90 feet, exceeding all you promised, and far surpassing the water wheel and force pumps which it has displaced. Its cost is small, it occupies but little space (2 square feet), and in mechanical detail is simplicity itself. I have much pleasure in recommending it as a cheap and efficient method of raising water."

**JOHN BLAKE,
ENGINEER, ACCRINGTON.**

THE GARDENERS' CHRONICLE
VOLUME for JANUARY to JUNE, 1877.
W. RICHARDS, 41, Wellington Street, Strand, W.C.

NOTICE.—In consequence of the very small competition (3 bunches), and the bad condition in which Golden Queen was shown at the Crystal Palace, the Judges withheld the Prizes offered. We propose therefore to offer the same Prizes of £5, £2 and £1 for the best single bunch of Golden Queen; also, the same amount for the best single bunch of Mrs. Pearson, at one of the autumn shows next year, probably during September, due notice of which will be given to these columns. J. R. PEARSON, Chilwell, Notts.

W. M. LEWIS GOAD (Messrs. Fraser, Goad & Co.) respectfully informs his numerous Friends that he has resumed Business on his own account, as a WHOLESALE and RETAIL SEED MERCHANT, at 7, Borough Market, London, S.E., and trusts that the kind support given to him for so many years will be extended to him in the future, as it will be his constant endeavour to merit a renewal of the confidence hitherto reposed in him.

LILY OF THE VALLEY.—I beg to inform all my numerous Customers, buyers of the above, that the Roots are unusually fine this year, and that I can furnish extra strong flowering roots at 4s. per 1000, carriage free to London. Orders are requested as early as possible.
ROBERT NEWMANN, Nurseries, Erfurt, Prussia.

CATALOGUES.—His Excellency Pierre Wolkenstein will feel greatly obliged if Nurserymen and Seedsmen will kindly send him their Catalogues. They should be forwarded (by post) to S. E. PIERRE WOLKENSTEIN, Secrétaire de la Société Impériale d'Horticulture de Russie, St. Petersburg.

BOILER, CLASS B, WITH TUBULAR BARS.

From E. G. HENDERSON AND SON,
Nurserymen and Seedsmen, Pine-apple
Nursery, Maida Vale, London, W.

April 24, 1877.

"DEAR SIRS,—We are in receipt of yours, and beg to inform you that the two Boilers you supplied us with answer very well, and we are so far very well satisfied with them, and have no doubt but they will continue to do their work well."

"Towerville, Helensburgh, near Glasgow,
September 22, 1876.

"DEAR SIRS,—Visiting the Exhibition at Manchester, in 1875, I saw the separate portions of your Boiler lying on the floor. On examination it appeared to me so happy an arrangement of surfaces, and so well calculated to utilise the heat of the furnace that I decided to have one should I ever be in need of a new Boiler. Since then I have substituted one of yours in place of a large Tubular Boiler, and the saving in fuel and labour is rapidly repaying the expense, and now I wish you to send me one of your No. 7, Class A, for heating my dwelling-house and hot-houses.—Yours truly,

"THOMAS WRIGHT."

From L. E. FLETCHER, Chief Engineer, The Manchester
Steam Users' Association.

Manchester, May 15, 1877.

"Mr. J. G. Wagstaff fixed one of his Patent Water Heating Boilers at the Schoolrooms attached to Rusholme Road Chapel, Upper Brook Street, Manchester, at the commencement of last winter. During the six months the Boiler has been at work it has given satisfaction, and heated the rooms well. It is very compact, and occupies but very little space.

"Oaklands, St. Albans, May 9, 1877.

"DEAR SIRS,—I find your Boiler, a No. 2, Class B, heating about 2000 feet of 4-inch pipes, that you supplied and set here last year, does its work with ease, and so long as the flues are kept clean and free from soot, it is most regular and easy of management. Your arrangement of the pipes is most satisfactory in heating all or disconnecting any of the six houses through which they pass.—Yours' obediently,

"C. DVMOKE GREEN."

"The Rectory, Droylsden, June 15, 1875.

"On the part of the Building Committee of St. Mary's Church Schools, Droylsden, I have much pleasure in stating that the Heating Apparatus fitted up in our new schools by you has given the fullest satisfaction. It has been tested by us during the severe season of '74 and '75, and has fully heated our large schoolroom, with ten class-rooms, so far proving quite satisfactory.—Signed on part of the Committee,

"SAMUEL MILLS, Rector.

From J. PEED, Roupell Park Nurseries,
Norwood Road, London, S.E.

May 3, 1877.

"DEAR SIRS,—I have had your Boiler at work here now about six months. In comparing it with the Top Flued Saddle I have here at work, I find it more powerful and economical, heating about double the quantity of pipe with the same quantity of fuel; namely, one chaldron of coke per week each.

"Yours very truly, "J. PEED."

From JOHN RIGG, Esq., Superintendent, Locomotive Department, Crewe Works, London and North-Western Railway Company.

"Albert House, Crewe, April 24, 1877.

"DEAR SIRS,—I have your note of the 16th instant, and can with pleasure testify to the suitability of the Hot-water Boiler supplied by your firm to me, in respect of its efficiency and economy, and the little attention needed to keep up a regular heat."

"Holcombe, Lancashire, May 12, 1876.

"Mr. J. G. WAGSTAFF.—The Churchwardens of Holcombe Church have great pleasure in testifying to the merits of your Patent Hot-water Apparatus. It has now been in use here sufficiently long to thoroughly test its qualities, and they have no hesitation in stating that they are perfectly well satisfied with it. The heat diffused through the body of the church is such that it is quite comfortable even in the depth of winter—a result never before obtained here. The cost of fuel compared with that of the Boiler lately in use is slightly less, the difference in effect very material.

"JAMES MEADOWCROFT, } Churchwardens,
"JAMES RENSHAW, }

GREAT WESTERN NURSERIES,
Kelvinside, Glasgow.

MR. A. VAN GEERT, NURSEYMAN,
Ghent, Belgium, begs to offer fine Plants of Budded
CAMELIAS, Indian AZALEAS, Ghent AZALEAS,
LATANIAS, CHAMEROPS, PHENIX and other PALMS,
table sizes; also SPIRÆA JAPONICA, fine clumps. Prices
on application.

The New CATALOGUE, just issued, sent to applicants.

New Exhibition and Decorative Fuchsias.

JAMES LYE, Clyffe Hall, Market
Lavington, Wilts, has the pleasure to offer the following
fine new varieties of his own raising, unrivalled for their high-
class qualities, excellent habits, and free-flowering properties:—

DARK VARIETIES.

Charming. Gem of the West. Mr. James Huntley.	James Lye. Royal Standard. Elegance.
---	--

LIGHT VARIETIES.

Beauty of Wilts. Lettly Lye. Blushing Bride.	Mrs. Huntley. Delicata. Miss Lye.
--	---

The above fine varieties have been most favourably reported
on in the *Gardeners' Chronicle* for June 9, and the *Gardeners'
Magazine* for June 23. A coloured illustration of Mr. James
Huntley, Lettly Lye, Mrs. Huntley, and Royal Standard,
appeared in the *Royal Magazine* for October.

A Descriptive List can be had on application. Plants are
now ready, and Orders will be executed as received.

Price the set of twelve varieties, £1 10s. per plant, 3s. Post-
office Orders payable to
JAMES LYE, Market Lavington Office.

Alhwick Seedling Grape Vine.

D. P. BELL begs to offer young plants of
the above Vine, the true variety as grown at Clive
House, from which the only exhibit has been made, and for
which he received the First-Class Certificate from the Fruit
Committee of the Royal Horticultural Society, December 6,
1876, regarding which the report of the Committee, as given by
the *Journal of Horticulture*, is as follows:—"The bunch is
large and heavily shouldered, with a stout stalk. The berry
stalks are stout, and the berries large and roundish oval,
frequently with sutural furrows; skin quite black and mem-
branous, covered with a fine bloom; flesh firm, tender, very
juicy, and sweet. It was unanimously awarded a First-Class
Certificate. This is a far superior fruit to Alicante, and will no
doubt prove to be a late-keeping variety of great value."

It is important that the public should know that this, the only
certificated variety (and therefore the original), has been exclu-
sively raised at Clive House, and cannot be had elsewhere.
Plants 15s. each.

The fruit now hanging on the parent Vine may be seen on
application.

To the Trade.

JOHN PERKINS AND SON
beg to offer the following, the whole of which have been
recently removed, and are fine healthy plants:—

ABIES DOUGLASSII, 4 to 5 feet, 18s. per dozen.

Hale Farm Nurseries, Tottenham, London.

The Best Hardy Bedding Plant.

CLEMATIS JACKMANII.—Flowers rich purple, 4 inches across, and so profuse as to completely cover the bed. Begins to bloom in June, and continues until severe frost. It is perfectly hardy, and the stools improve annually. The only secret of success is a rich soil, to keep up free growth. Strong plants in pots, 12s. per dozen; extra strong plants, 2 years old, 15s. per dozen. Other sorts of Clematis and Climbers in great variety. Descriptive LIST on application.
RICHARD SMITH, Nurseryman, Worcester.

To the Trade.

MESSRS. LEVAVASSEUR AND SON, Nurserymen, Ussy, Calvados, France, have an immense stock of Seedling FOREST TREES, Hardy, Coniferous, and other SHRUBS, for transplanting and transplanted; several millions of 1-year THORN. Priced CATALOGUES may be had of
Messrs. R. SILBERRAD AND SON, 5, Harp Lane, Great Tower Street, London, E.C.

FOR SALE, a Collection of Valuable ORCHIDS, also a Quantity of PINES and SUCCESSION PLANTS. Apply,
Acacia Hall, Dartford, Kent.

Vines—Vines—Vines.

B. S. WILLIAMS begs to announce that his VINES this year are in unusually fine condition, and are now ready for distribution.

NEW LATE-KEEPING BLACK GRAPE, "ALNWICK SEEDLING."—This Grape was exhibited before the Fruit Committee, South Kensington, February 6, 1876, under the name of Clive House Seedling, a name the Committee have since thought fit to alter. The following is the description given by the Fruit Committee:—"It is a seedling between the Black Morocco and an unnamed variety raised at Wortley. The bunch shown was of fair size and well shouldered, and the berries large, oval in form, and jet black in colour, with a thick skin. The flavour was decidedly good, partaking of the rich sparkling flavour of the Black Morocco, but much sweeter. It has kept well till February, and will, no doubt, keep longer and prove a better Grape for general cultivation than the Black Alicante." This has been awarded a First-class Certificate. The stock offered is from the original plant. Early orders are respectfully solicited, as the stock is limited. Price 21s. and 42s. each. For Detailed List see BULB CATALOGUE.

NEW FIG, "HARDY PROLIFIC."—The fruit of this hardy Fig is about the medium size, Pear-shaped, rather tapering towards the stalk. The flesh is very sweet and luscious. It was introduced from France some few years ago, and has proved itself perfectly hardy. It must become a general favourite, as it is a very abundant bearer, either in pots or in a cold house, as well as on an open wall. It also ripens earlier than any other variety we know of. Price 10s. 6d. each. Extra sized fruiting plants, 21s. each.

B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London, N.

Vines and Strawberries.

"Plant now to ensure a full crop of fruit next season."
FRANCIS R. KINGHORN begs to announce that his stock of VINES, including all the leading varieties, is very extensive, and in excellent condition this season. The Canes are very fine, well ripened, and perfectly free from disease. Strong Planting Canes, 3s. 6d. to 5s. each; strong Fruiting ditto, 7s. 6d. to 10s. 6d. each. Also his collection of STRAWBERRIES includes all the most popular kinds, and are ready for immediate planting. Price, in small pots, 16s. to 20s. per 100; from the open ground, 3s. to 5s. per 100.
Less numbers than 100 of any variety can be had, if desired. Prices to the Trade and LISTS post-free, on application.
Sheen Nursery, Richmond, Surrey.

VIOLETS, SWEET VIOLETS.

MARIE LOUISE, double, light blue, white centre, flowers very free and continuous from September to May.
VICTORIA REGINA, large single Violet, very fine.
WHITE CZAR, the best white.
BLANDYANUM, large double Violet.
KING OF VIOLETS, large double Violet.
REINE DES VIOLETS, large double white.
NEAPOLITAN, double lavender.
" single lavender.
Strong clumps of the above 6s. per dozen, 40s. per 100, suitable for potting in 48-inch pots, or forming beds and masses in flower gardens. Now is the time to plant to ensure flowers all winter and spring.
BELLE DE CHATENAV, new double white, 1s. 6d. each.
PATRIE, new double blue, very free flowering, 1s. each.
One small plant of the ten varieties free by post 5s. 6d. Trade price on application.
FREDERICK PERKINS, Nurseryman, Regent Street, Leamington.

CEDRUS DEODARA, CEDRUS ATLANTICA, CUPRESSUS

LAWSONIANA, PICEA NOBILIS,

And a large Assortment of the finest Ornamental Plants of other descriptions.

Particulars will be given in future Advertisements, meanwhile Catalogues are being prepared, and the Stock to be Sold may be seen at

THE NURSERIES, INVERLEITH ROW, EDINBURGH.

P.S.—The Annual CATALOGUES of FOREST TREES, ORNAMENTAL TREES and SHRUBS will be published at the usual time, and Special Offers to Large Buyers made upon application.

DRACÆNA GOLDIEANA.

One of the most magnificent ornamental-foiled plants ever introduced, and altogether unique in character and aspect. It is a native of Western Tropical Africa. The plant is of erect habit, and the stems are closely set with stalked spreading leaves, the petioles of which are of a grayish colour; the blade of the leaf is cordate-ovate acuminate, with a yellowish-green costa, and marbled and irregularly

banded with dark green and silver-gray in alternate straight or furcate bands, the colours being about equally distributed. The back of the unfolded leaves is a pale reddish purple colour. It is without doubt one of the most superb of ornamental stove plants, and indispensable in all first-class collections.

Price, 5, 7, and 10 Guineas each, according to size.

BOWENIA SPECTABILIS SERRULATA.

This is a most distinct and remarkable plant, *Bowenia* being the only known Cycad having bipinnate fronds. It has a short thick caudex, from the crowns of which are developed its large and singularly handsome leaves. The petioles are long, slender, roundish, and of a dark green colour; the lamina is bipinnatisect and spreading, the

pinnules are firm in texture, obliquely falcato-lanceolate with an acuminate point, differing materially from the normal and only other known *Bowenia* in having their margins distinctly and prettily toothed or serrated. Any description must fail to give an adequate idea of the distinct and striking character of this ornamental Australian plant.

Price, 2 Guineas each.

Mr. WILLIAM BULL has much pleasure in offering the above Plants, which are two most remarkable introductions, and from their sterling merit two of the greatest acquisitions he has ever had the pleasure to announce.

WILLIAM BULL, F.L.S.,

Is also offering the following NEW PLANTS:—

ARALIA FILICIFOLIA
COLEUS PICTUS
CROTON HENDERSONI
CROTON REX
CURMERIA WALLISII
DIEFFENBACHIA CHELSONI

DIPLADENIA REGINA
DIPLAZIUM ARNOTTII
HIBISCUS (ROSA-SINENSIS) COLLERII
IRIS ROBINSONIANA
PANAX LACINIATUM
SADLERIA CYATHEOIDES

SMILAX SHUTTLEWORTHII
SIX NEW DRACÆNAS
TWENTY NEW DOUBLE-FLOWERED
IVY-LEAVED PELARGONIUMS
NEW REGAL PELARGONIUM—PRINCE
OF WALES.

For Descriptions and Prices of the above, and various other New Plants, see Mr. W. B.'s Illustrated Catalogue, price 1s.

ESTABLISHMENT FOR NEW AND RARE PLANTS,
KING'S ROAD, CHELSEA, LONDON, S.W.

BOULTON & PAUL,
HORTICULTURAL BUILDERS,
NORWICH.

No. 75.—MELON FRAMES and FORCING FRAMES.

The largest Stock in the Kingdom, ready to be despatched on receipt of order.

These Frames are made of the best red deal, thoroughly seasoned, and fitted by first-class workmen: 24 in. high at the back, 13 in. high in front; painted three coats of good oil colour, glazed with best 21-oz. glass, every pane of which is nailed in and bedded in with putty—the best method of glazing known, and adopted by the most eminent Builders and leading Nurserymen (see *The Garden* for January 13, 1877, p. 30). Iron handles to each light, and an iron strengthening bar across. Each light is 6 ft. by 4 ft., and 2 in. thick.

CASH PRICES (Carriage paid).

Special Notice.—Carriage paid to any Railway Station in England. Also to Dublin, Glasgow, and Edinburgh, on Orders of 45s. and upwards.

PIT LIGHTS and SILLS for BRICK WALLS on EARTH BANKS.

PIT LIGHTS AND FRAMES.

Complete for fixing on Brickwork, made in two sizes of lights to work 6 feet by 4 feet 2 inches thick, 7 feet 6 inches by 4 feet 2½ inches thick, lights glazed with 21-oz. British sheet glass, painted four times, sills 4½ inches by 3 inches, with bearers and parting pieces complete, with screws, wrought-iron handle to each light, and strengthening bar across.

CASH PRICES.

Carriage paid to any Railway Station in England and Wales, also to Edinburgh, Glasgow, Dublin, Belfast, or Cork.

SILLS or FRAMES.

FINDERNE'S FLOWERS.

"Time, Time his withering hand hath laid
On battlement and tower,
And where rich banners were displayed,
Now only waves a flower."

ONE of the greatest charms of an old country lies in its buried history. Sir Bernard Burke informs us, in his *Vicissitudes of Families*, that in the course of his researches a village legend or peasant tale have frequently supplied the clue that guided him in an intricate path of genealogical discovery. In Ireland particularly, the local memories of the people are wonderfully vivid and correct. The details may be exaggerated, confused, and inconsistent, but they are true in the main, and this local sentiment attaching to every inch of earth in our mother country may in part atone for her limited number of acres, compared with those of her colonial possessions, where the ground, rich as it may be, is not endowed with any charm of life, and where no departed breath of predecessors sighs in the wind, or whispers in the shaken leaf.

As a rule, families have not retained their estates and names for many centuries. Mr. M. A. Lower mentions, in the *Worthies of Sussex*, that only three families in that county have retained their hereditary property and their names for a period of 350 years. A common calamity which overtakes them is, that they become extinct; or, they terminate in daughters whose offspring, as a rule, bear another surname. An acorn sown and protected in a Sussex park may, therefore, be expected to shelter three families of owners. In the hamlet of Finderne and parish of Mickleover, four miles from Derby, a patch of "garden flowers grown wild" in a field, have outlived the family whose garden they adorned.

For nine generations the distinguished Findernes resided at the hamlet which retains their name. They fought in the Crusades, at Cressy, and at Agincourt, and their territorial possessions were large. Few families were held in higher estimation than the Findernes; their mansion had been rendered by restoration one of the quaintest and largest in the Midlands; they had been frequently High Sheriffs, and sometimes Rangers of Needwood Forest and custodians of Tutbury Castle. They had matched with the best families, and within the church, which still stands, and which was once the family chapel, their dust lay thick, their memorials were numerous upon the walls, while for centuries each epitaph and monumental brass within the sacred building was in honour of a Finderne.

In 1850, Sir Bernard Burke, searching for a pedigree, visited the village. He sought for the hall, not a stone remained! He entered the church, not a record of a Finderne could be distinguished! The sons of this race were brave, their daughters fair, but the frequent fate of families had overtaken them. The male line having failed in the sixteenth century, the last heiress had married a Harpur, and oblivion had fallen upon the family name.

On the occasion of Sir Bernard Burke's visit, "Finderne's Flowers" were the only mementos of the ancient family that still remained. In the twelfth century Sir Geoffrey Finderne had joined a crusade, bringing from the Mediter-

ranean, as many English gentlemen did, some knowledge of agriculture and gardening, and some seeds and floral specimens—including no doubt Lilies, which were dedicated—as indeed all flowers were—to the Virgin. And in a field near the church, in 1850, an old man pointed out the faint traces of terraces and foundations, and there, said he, pointing to a bank, “are the Finderne’s flowers, brought by Sir Geoffrey from the Holy Land, and do what we will they will never die!” That there is poetry in such prose, and language in flowers, as well as beauty, we need not urge. *H. Evershed.*

New Garden Plants.

PESCATOREA BACKHOUSIANA, n. sp.*

We had till now only two *Pescatoreas* with coarse, warty asperities on the lip’s blade standing in front of the crescent-shaped lamellar callus of the base. One is the well-known *P. cerina*, the other the very rare *P. coronaria*, known in Europe now by two dry flowers, sent in spirits by Mr. Wallis. The first is of a waxy ochre colour and has its sepals much cuneate at base, much dilated before the apex, and an angular keel at the very base of the lip. The second one is unknown in its colour, but may be immediately recognised by the most surprising feature that the lip blade has not only the rough warts of *P. cerina*, but very numerous hairs. It is quite unique. It may be No. 196 of Mr. Wallis’ itinerary notes, and if so it is coloured purplish with greenish apices to the sepals and petals, and it has a lip whose general colour is that of the human skin (viz., North European I hope), with the callus ring of the darkest carmine. Our new species is very distinct from both. It has no hairs on the lip, hence it is not *P. coronaria*; it has a totally different shape of lateral sepals (tapering gradually from the base to the apex) and no angular callus at the lip base, and, let me add, the colours are totally different. Hence it is new, as far as human certainty reaches. The flower is rather large, equal to that of a good, well-fed *P. cerina*. The ground colour is whitish or cream coloured. All the anterior parts of the sepals and petals are of a purplish violet that is not so warm as in the best varieties of Mr. Day’s unrivalled *Pescatorea*, though it may also appear by-the-by in this one. The lip is cream coloured too, with a deep yellow hippocrepic callus of nineteen ribs running out in angles, having brownish middle lines to the keels. The warted part is sulphur coloured, the exterior light purplish. The column is purplish behind, and its front-side is yellowish-white, covered with innumerable small purplish drops excepting an area at the base that is nearly free of them. There is the usual apiculus on the foot of the column. It is a splendid thing. I know nothing of the origin, yet I suspect it may come from Ecuador. It is dedicated to the lucky possessor, Mr. J. Backhouse, who preserves a warm love for Orchids, and appears unusually successful with *Pescatoreas* and *Bolleas*. *H. G. Rehb. f.*

CYPRIPEDIUM PATENS (*Cypridium barbatum* × *Hookerae*).†

Once more one of Mr. Seden’s hybrids, raised at the Royal Exotic Nursery of Messrs. Veitch, by applying the pollen of *C. barbatum* to *Cypridium Hookerae*. The leaves are just intermediate between those of the two species, being not so brilliant as in *C. Hookerae*, nor so indifferent as in *C. barbatum*. The long peduncle of *C. Hookerae* is rather kept, but its value is not increased by the flower itself being rather large, and its colour not being so dark as in the just-named species. The green ovary very much exceeds the very short bract. The upper sepal is rather semi-ovate acute, green in its disk, white on the borders.

* *Pescatorea Backhausiana*, n. sp.—(Asperilingues.) Sepalis oblongis obtuse acutis, sepalis lateralibus a basi aequaliter apicem versus angustatis; sepalis summo ac tepalis apice angulato; labello energeticis trilobis, lobis lateralibus erectis obtusangulis, lobo antico transverso trilobulo, lateribus reflexo, convexo; callo hippocrepico ex lamellis angulatis undecim; disco anteposito papulis apice verruciferis nullis seriatis onusto angulo exsistente in basi labelli nullo.—*Zygoptalum Backhausianum*. *H. G. Rehb. f.*

† *Cypridium patens*, n. hybr. (*Cypridium barbatum* × *Hookerae*).—Folii tessellatis; pedunculo bene villosulo longe exserto; bractea ovario villosulo multo breviori; sepalis superiori semiobovato triangulo, sepalis inferiori anguste triangulo; tepalibus ligulatis obtuse acutis vix apice dilatatis; labello ore retuso; cornubus utriusque parvulis vix prominulis; staminodii transverso semilunari; utriusque anticæ semilunari forcipato apiculis in sim.—In horto Veitchiano a dom. Seden artificialiter obtentum. *H. G. Rehb. f.*

The internal veins are green, the external ones green at the base and purplish violet above. The inferior sepal is triangular, whitish, with dark veins, and quite covered by the lip. The petals are far more dilated at the top, not wavy before the base. Their colour is purplish violet, that is by no means so warm as in *C. Hookerae*. The base is greenish in part, and much more so in the inferior half. The lip is dark brownish violet. The staminode semilunar, with two coloured inflexed half-circular teeth at the side and a little apiculus in the sinus, brownish at edges, with green nerves in the disk, covered with small hairs. *H. G. Rehb. f.*

NEPHRODIUM (EUNEPHRODIUM) LUCIDUM, Baker, n. sp.*

During the last three or four years a great deal has been accomplished in the exploration of the Ferns of Madagascar. By Mr. William Pool and Miss Helen Gilpin 150 species have now been gathered in the elevated district of the interior of the island, and of these about one in three prove to be new species, the other 100 being identical with previously known Mascarene or cosmopolitan subtropical or temperate types. The present plant, which was given by Mr. Pool to the Kew collection in 1876, and which Mr. Smith has just grown up to the fruiting condition, is a fourth new species of *Nephrodium*, in addition to three which I have already described in the 15th volume of the *Journal of the Linnean Society*, in a paper commencing at p. 411. In general habit it closely resembles the Japanese *N. sopheroides*, Desv., from which it may be known by its glabrous fronds of a bright green colour and narrow pinnae with segments containing much fewer veins in a group. It is to be hoped that this is only the first of a long series of novelties to be added to our stock of cultivated species from the island, now that it is being explored and its inhabitants gradually civilised. There is no part of the world at the present time that offers a more promising field for a botanical collection.

Rhizome short-creeping. Basal scales few, small, brown, lanceolate, membranous. Stipes contiguous, 1–3 inches long, slender, bright green, with a few small deciduous adpressed membranous scales. Lamina oblong-lanceolate, bipinnatifid, moderately firm in texture, bright green on both surfaces, glabrous throughout, reaching 12–15 inches in length, 5–6 inches broad at the middle, narrowed gradually from the middle to the base. Pinnae in 12–20 pairs below the pinnatifid apex, spreading, sessile, linear, the largest central ones 2½–3 inches long, ¼–½ inch broad at the middle, cut down to the rachis into oblong-quadrate contiguous erecto-patent secondary segments ¼ inch broad, of which the lowest anterior one is uniformly much larger than the others; veins 2–3-jugate in the ordinary secondary segments, 4–5-jugate in the enlarged lowest anterior segment of the pinnae, pellucid, only the lowest pair anastomosing. Sori small, apical on the veins, so that those of neighbouring groups touch one another. Involucre small, glabrous, membranous, evanescent. *J. G. Baker.*

COTYLEDON (UMBILICUS) PESTALOZZE † = *Umbilicus Pestalozze*, Boissier, *Flora Orientalis*, ii., p. 771.

We received a flower-panicle of this fine hardy succulent plant from Mr. Maw, of Broseley, a month or two since, under the name of *Sedum sempervivoides* (?). The query was certainly justified, as the plant is very clearly a *Cotyledon*, of which *Umbilicus* is now made a section; and on comparison with specimens collected by Balansa (705) in Cilicia it became evident that Mr. Maw’s plant was the same as described by M. Boissier under the above name.

It is more than probable that this plant is a mere variety of *C. (U.) Libanoticus*, from which it differs mainly in the stem-leaves being rather broader towards their free ends. In any case, we have here an attractive plant sure to find favour with lovers of succulent and rock plants. Mr. Smith’s figure (fig. 89, p. 457) is so faithful that no lengthened description is necessary, the botanical details cited in the foot-note being sufficient to establish its identity. Here, then, it need only be said that the plant is covered with glandular hairs of a reddish colour, and that the flowers are of a pink hue. *M. T. M.*

* *Nephrodium (Eunephrodium) lucidum*, Baker, n. sp.—Rhizomate breviter reptante, paleis paucis parvis brunneis lanceolatis; stypite brevi parve paleacea; fronde oblongo-lanceolata bipinnatifida utriusque glabro laevide viridulo; pinnis sessilibus linearibus, segmentis secundariis oblongo-quadrate erecto-patentibus contiguis integris, inferiori anteriori reliquis majori, venis simpliciter pinnatis, venulis 2–3 vel in pinnulam anteriorem basalem 4–5 jugis infimis solum anastomosantibus; soris parvis quad venis apicalibus, involucre parvo glabro membranaceo.

† *Umbilicus Pestalozze*, Boissier, *Flora Orient.* 2, p. 771.—“Glabrus plus minus pubescens glandulosus; foliis radicalibus, spatulatis obtusis basi cuneato-attenuatis margine obsolete denticulatis; caulibus obovato-oblongis; paniculae glandulose hirta racemosa; floribus sub secundis; corollae pallide rosae calyce 2½-plo longioris ad medium fissae laciniis lanceolatis acuminatis 2.—Hab in Caria, Syria, Cappadocia, &c. Valde affinis *U. Libanotico* a quo glaucedine praesertim differt; folia caulina praeterea latiora magis spatulata. An tamen hujus varietas?—Xylogr. most., fig. 80, p. 457.

THE NEW TUBEROUS-ROOTED BEGONIAS OF 1877.

HAVING during the summer and autumn now drawing to a close continued my trials and comparisons of all the new varieties of the above-named highly ornamental and continuous-blooming genus and, having bedded out over eighty named varieties, I have now to report as to the respective merits and demerits of the thirty-one new varieties sent to me from various sources (principally Continental). I have grown the whole of these in the open air, and carefully compared them with the fine introductions of previous years, concerning which I had somewhat to say at the end of the outdoor blooming season of 1875 and 1876 in the leading horticultural newspapers. My remarks, I may venture to hope, have been of some use in guiding amateurs in the selection of a good assortment of these beautiful flowers, which, in the opinion of all who have seen them here this summer, are quite unequalled by those of any other plant for affording an unbroken continuance of brilliant bloom from the middle of June till the middle of September in the open ground, and for a further month or six weeks after being lifted into pots for the greenhouse, before they finally go to rest for the winter towards the middle of November. Of the twenty-six novelties above mentioned eight came to me from Van Houtte, of Ghent, being all seedlings raised in the establishment from which we have already received so many fine varieties. This year’s lot, however, was of very unequal merit, three only out of the eight being of first-rate excellence, one other, with large and sometimes semi-double male blooms of a pleasing and uncommon deep bluish colour, having faults in habit of growth of considerable gravity; the other four were either insignificant or otherwise comparatively worthless. Seven varieties, three of them double flowered and four single, came to me from M. Victor Lemoine, of Nancy; all of these, with the exception of one of the doubles, were very good, as might be expected from the source from whence they came. From Messrs. Thibaut & Keteleer, of Sceaux, came six varieties, all of them raised by the gardener of a neighbouring private gentleman, Fontaine by name, and all of them were of first-rate excellence, two of them indeed being in my opinion the most beautiful varieties yet obtained by any raiser; these are named *Lelia* and *Exposition de Sceaux*—the latter variety, however, is I believe not yet in commerce. Another of this set is curiously enough identical with a very fine variety sent out by M. Van Houtte in 1875. From M. Deleuil, of Marseilles, came four varieties of very fair merit indeed. From Mr. Vincent, of Bougival, came one very fine variety. From Messrs. Veitch, of Chelsea, came one variety which did not bloom at all. I shall now proceed to describe these new varieties *seriatim* in the above-named order, as briefly as possible, from notes taken down as each arrived at its full development, and carefully corrected afterwards when any point previously noted was found to need correction.

VAN HOUTTE’S VARIETIES.

1. *James Backhouse*.—A most beautiful variety, with full-sized light scarlet blooms, which when fully expanded are perfectly flat. The habit of growth is low and spreading, and the flowers, which are produced in great abundance, are well raised above the foliage. This is a really first-class variety, and should be in every choice collection.

2. *Laurant Descours*.—A most lovely variety of low and spreading habit of growth, with large and handsome foliage, and producing with great freedom on slender footstalks, well elevated above the foliage, an abundance of large and perfectly formed flowers of a clear bright rose colour, the males of which when fully expanded are also perfectly flat. A variety of first-rate excellence.

3. *La Baronne Hrabov*.—A light foliaged, compact-habited variety, producing full-sized, well shaped cupped blooms of a lovely deep shade of crimson, borne on slender footstalks and apparently not over freely produced. This is considered by its raiser one of his finest varieties.

4. *Notaire Beaucarne*.—This is supposed to be a semi-double variety, and the male blooms usually have from three to five extra petals. The flowers are of large size and good substance, of a deep bluish colour, produced on long and pendulous footstalks. This variety, though by no means perfect as a florist’s flower, yet from its size of bloom and somewhat uncommon shade of colour is likely to find many admirers.

5. *La Baronne Léon Legay*.—A strong, vigorous habited, upright growing variety, with medium-sized

blooms of a whitish colour when they first show themselves, but which ultimately turn into a good clear pink colour. This, however, cannot be considered as more than a good second-rate variety, with which one of the choice unnamed seedling sent me by M. Lemoine is identical.

6. *Madame Meyer*.—A low-growing, branching-habited, free-blooming variety, with small and inconspicuous flowers of a pale blush colour. It is of not more than third-rate merit, and hardly worth a place in

M. LEMOINE'S VARIETIES.

1. *Louis Van Houtte* (double).—This is of dwarf compact habit of growth, the male blooms fully and evenly double, and of a deep shade of salmon colour; a beautiful variety.

2. *W. E. Gumbleton* (double) is of dwarf and compact habit of growth, with fully and evenly double male blooms of a paler salmon shade than the last-named variety, borne on rather slight footstalks well raised above the foliage. The blooms are about medium-size.

large and perfectly formed blooms, both male and female of a deep clear rose colour, resembling somewhat those of *Diamant*, sent out by the same raiser last year, but much deeper in shade and more perfect in shape. The foliage is of a peculiar glaucous metallic hue. This variety should be in every choice collection.

6. *Abondance*.—A compact-growing variety, producing medium-sized cup-shaped blooms of a dark claret colour, borne on slender perpendicular footstalks, well elevated above the foliage, and of about medium size.

7. *W. E. Gumbleton* (single) is an exceedingly fine variety, of stout and upright habit of growth, producing plentifully, on strong footstalks well raised above the foliage, most beautifully cupped blooms of the most brilliant shade of scarlet, somewhat resembling those of a small Tulip in shape. This is considered by M. Lemoine as the most distinct and beautiful variety he has yet sent out. During the latter part of the season all the blooms are male.

M. FONTAINE'S SIX VARIETIES.

1. *Monsieur Bienaimé* is an upright growing variety, of exceedingly vigorous habit of growth, producing an abundance of fully sized handsome blooms, of the same colour as the old variety *Intermedia*, but of a deeper shade and larger size, and much greater substance. The female blooms, also, are unusually fine and perfect in form. Were it not that this fine variety unfortunately drops about half its male blooms in an unopened bud state during the earlier half of the season, it would be of quite first-class merit.

2. *Adolphe Fontaine*.—This is a very fine variety, but is curiously enough identical in every way save a slight variation in the foliage with Van Houtte's fine variety of 1875, Paul Masurel, and therefore need not be added to any collection already possessing that variety.

3. *Monsieur Pigny* is of compact and rather hard and stiff habit of growth, with dark hairy foliage, resembling that of Lemoine's *Oriflame*. Its flowers are of good size and substance, resembling in colour, but being a decided improvement in shape on, those of Lemoine's *C. Glijm*. They are somewhat sparingly produced.

4. *Exposition de Sceaux* is a most beautiful variety of erect growing and free blooming habit, producing extra large and most beautifully cupped male blooms of a lovely shade of deep and intense rose colour, closely resembling Van Houtte's fine variety of 1874, Charles Raes, in shade, but of infinitely finer form and substance. The female blooms, also, are quite exceptionally fine. This is unquestionably one of the finest *Begonias* that has yet been raised, and when distributed should be in every choice collection.

5. *Lelia* is also an exceedingly beautiful variety, in habit of growth and fine form and substance of its male blooms somewhat resembling the last-named variety, though the blooms are not quite so fully cupped in shape. The colour is a most lovely deep shade of crimson, somewhat resembling Veitch's *Kallista*, but of infinitely finer form and substance. It is also an exceedingly free bloomer, and should be in every choice collection.

6. *Hebé*.—This variety is considered by its raiser to be one of his finest hybrids, but unfortunately it did not make any healthy growth till late in the season, so that I was unable adequately to form an opinion as to the real merits of the variety. The blooms, as far as I could judge, are light red, resembling *Vesuvius* in shade, and of excellent shape and substance.

M. J. B. A. DELEUIL'S FOUR VARIETIES.

1. *Carnicolor* is a variety of close-growing tufty habit, with most distinct and ornamental foliage, scimitar-shaped, and curiously crimped at the edges, and producing blooms which are almost white when they first appear, but which afterwards turn to a deep nankin outside, and a clear flesh colour within; the male blooms are of large size, but rather thin in substance. This variety is only suited for pot culture in the house, for when grown in the open air all the male blooms drop in an unopened bud state, which does not happen when grown under glass. This is an exceedingly distinct variety, being, with the exception of Van Houtte's *President Schlachter*, the only one yet sent out of this peculiar shade of colour.

2. *Violetta* is a variety of medium height, and somewhat glaucous foliage, producing on tall and somewhat weak footstalks fairly-sized blooms, rather thin in substance and poor in form, but of a pleasing and novel shade of rosy violet; a variety of about second-class merit.

3. *Clopatre*.—A variety of spreading and branching habit of growth, with large flowers of a light red colour, of good shape, but not much substance. The female blooms of this variety are a good deal above average merit.

4. *Bayard*.—A fine variety of medium height of growth, producing large and well-formed blooms on rather pendulous footstalks, the exterior of which in shade resembles that of Veitch's fine variety *Acme*, the interior

FIG. 89.—COTYLEDON PESTALOZZÆ, WITH SECTION OF FLOWER, POLLEN-GRAINS, AND GLANDULAR HAIRS.

a collection, save for its dwarf habit of growth and freedom of flowering, which may perhaps recommend it to some growers as an edging to a large bed, with taller growing varieties in the centre.

7. *F. M. Dos Santos Viana*.—A variety with pointed dark green marbled foliage, in the way of *Pearcei*, with medium-sized blooms, of a dull red outside and of a deep orange inside, which, however, soon tarnish on exposure to the sun, as do other inferior varieties. It can be considered as a variety of second-rate merit only.

8. *James Duncan*.—An utterly worthless variety, of a dull and washy yellow colour. How it came to be named at all I am altogether at a loss to understand.

3. *Argus* (double) is a light red variety, with an unevenly duplicated centre to the male blooms; a variety of only third-rate merit.

4. *Incendie*.—A pleasing variety, of low and tufted habit of growth, producing medium-sized blooms of good form and substance, and of a dazzling light orange-scarlet shade of colour, which, however, unfortunately burns and tarnishes when exposed to the sun, which completely spoils the beauty of the blooms after they are a day or two expanded. This variety may not be thus affected when grown in pots for the greenhouse, where its great brilliancy of colour should make it an acquisition.

5. *Jules Janin*.—A really beautiful variety, with

being of a lighter orange shade. The female blooms are also good.

M. J. VINCENT'S ONE VARIETY.

Reine de Bourgival.—An exceedingly floriferous variety, of quite a novel and most acceptable shade of colour, the blossoms, which are of an oblong cupped shape, being clear cream colour within, the outer middle petals being of a light red. This is admirably suited for the centre of a bed from its upright habit of growth, and the fine contrast it forms to nearly all other varieties. *W. E. Gumblaton*.

TOMATO AND CUCUMBER PRESERVES.

It being an acknowledged fact that our stock of hardy fruits is very small this season, housewives who are old-fashioned enough to prefer home-made preserves are getting anxious as to the possibility of filling up the shelves of the store closet with something approximating to the ordinary quantity of *confitures*. Pumpkin and Vegetable Marrow have been already strongly recommended in the columns of the *Gardeners' Chronicle*, as forming the foundation of a cheap and wholesome jam, and, in the view of the dearth of hardy fruits and superabundance of certain kitchen garden crops, we suggest two other vegetables, which make excellent preserve—Cucumbers and green Tomatos. Although we cannot extol these preparations to the extent of comparing them to confections of rich luscious Plums, or ripe juicy Apples, they are wholesome and palatable, and an excellent and economical substitute, in seasons of scarcity.

Without entering into a discussion as to the merits or demerits of the British, as compared to the Continental *cuisines*, it will, we think, be readily admitted that we are somewhat restricted in our ideas as to the value of various preparations of cheap and homely dainties in the way of vegetable diet, and, once having exhausted the commonly received and well known recipes for boiling or pickling ordinary kitchen garden crops, it is but seldom, even though blessed with a superfluity of two or three sorts, that any novel methods of utilising or preparing them are considered. Thus, while other nations, more especially the French, waste nothing, we throw aside as refuse vast quantities of food which might, by artistic preparation, become dainty dishes. This autumn, which has given us such large quantities of Vegetable Marrows in the London market, has also supplied us with a superabundance of small Cucumbers; when remarkably low in price, as they have been this year, these fruits cut up and pickled are often substituted for the more delicately flavoured and more expensive Gherkin, as well as making an excellent pickle, they may be prepared as a pleasant sweetmeat, being not only grateful to the palate but exceedingly pretty as a dessert dish.

Cucumbers as jam might be preserved in a manner similar to that advised for a Vegetable Marrow in a recent number of this journal, save that moist sugar imparts a coarse rough taste; pounded loaf sugar should always be employed in preserves—the very trifling extra expense is fully repaid by the superiority of flavour.

The following method of preparation is excellent although somewhat elaborate; it is as applicable to Melons as to Gherkins or Cucumbers. Take green fresh Cucumbers, free from seed, place them in a jar of strong salt and water, with Vine leaves on the top, set them by the fireside until they are yellow, then wash and place the Cucumbers in a pan of water in which a little alum has been dissolved, cover with Vine leaves, boil until tender. When taken off the fire they must be allowed to stand in the liquor until cold; they should then be quartered or cut in rounds about an inch in thickness, all the seeds being scooped out. The Cucumbers should then be placed in cold spring water for twenty-four hours, changing the water twice. The syrup in which the Cucumbers are to be boiled should be prepared in the following manner:—To each pound of loaf-sugar half an ounce of bruised ginger, with as much water as will wet it; boil, and when free from scum, but still boiling, put in the rind and juice of a lemon. When quite cold, pour the syrup over the Cucumbers, having previously drained the latter from the cold water. A spoonful of rum gives the West India flavour, and when the fruit is to be served at the dessert-table the best crystallised white sugar should be powdered over the fruit in the dish. One ounce of powdered alum is sufficient for a dozen

Melons or Cucumbers. The Vine leaves may be used or not according to taste.

The present has, we fear, been a disastrous season for outdoor crops of Tomatos, and there are no doubt a far greater number of half-grown green fruits than of full-sized ripe ones, in the majority of kitchen gardens. Under these circumstances many persons will be glad to learn that green Tomatos make very good jam, so good indeed that we heard it extolled as equal to Green Gage. Without saying quite so much in its favour, we may truly vouch that it is a very tasty preserve, more distinctive in flavour, more wholesome and more economical than the manufacturers' jams, now so commonly used.

The Tomatos should be gathered when quite dry, and placed in the preserving pan with an equal quantity, weight for weight, of pounded loaf-sugar; sufficient lemon-juice must be added to give piquancy to the flavour, as the Tomatos alone would be flat. Ginger may also be added, and some blanched kernels of Plums or Peaches not forgotten; these latter add much to the palatableness of the jam, and give it the appearance, as well as the flavour, of Green Gages. *J. J.*

OAK GALLS.

HAVING had opportunity during the last year of observing the different galls on the Oaks in the neighbourhood of Isleworth a note of the species found there (within 9 miles of London, and in some degree within the influence of its smoke), compared with those of West Gloucestershire, near Chepstow, may possibly be of some interest to those fond of the study of gall localities and peculiarities of growth. As the synonyms are sometimes numerous, and there may sometimes be doubt which name is commonly adopted, I have endeavoured to give a short description as well as the English name where possible, that there might be no uncertainty as to the species intended.

Round Isleworth the common round marble gall of *Aphithrix lignicola* appeared plentifully with great variety of size; the Artichoke gall of *A. gemmæ* was moderately plentiful, but not healthily developed. This gall is easily distinguishable by its overlapping leaf-like growth, giving it an almost exact resemblance to a miniature Artichoke growing in the axils of the leaves, and in all the specimens I have seen last year the oval central cell containing the future insect has been only partially developed or else absent, that is, never formed.

Of the root-gall of *A. radicis* I have only seen a few specimens. Where this gall thrives it may be found as an irregularly shaped, spongy, or woody mass (according to its age), formed inside of an aggregation of cells, and growing at the ground level on the rough bark of Oak roots, often close to the tree, and attaining the size of a large Walnut in its husk, or more, but the specimens growing here have been all small and stunted.

The "woolly gall" (*Andricus ramuli*), which catches the eye from its resemblance to a little bunch of cotton-wool or sheep's-wool, fixed in the axil of a leaf, has appeared sparingly, but *Andricus curvator* has been plentiful. In this case the gall appears externally merely as a portion of the leaf-vein swelled out of all shape, whilst inside is a cavity containing a very small brown oval cell, adhering only by a slight attachment at one point to the side of the hollow chamber, and enclosing within it the future insect. There were also a very few specimens of *Andricus quadrilineatus*, a small green oval gall, longitudinally lobed, sparingly distributed on the hanging inflorescence.

The Currant-gall, *Spathegaster baccarum*, has been fairly plentiful and finely developed, but more so in the variety affecting the leaves than that of the elegant and brightly coloured Currant-like bunches on the pendent inflorescence, from which it takes its name.

The common Oak-apple (*Teras terminalis*) has also been moderately plentiful and well grown.

Of *Cynips longiventris* there have been a very few galls, whilst the rare kind of *C. ferruginea* (a small form, somewhat resembling a hardened and pointed leaf-bud) has only been represented by two or three specimens, as well as *C. noduli*, an external cell formed in the spray, of which the external indications are so slight as almost to require the aid of a glass to discover them.

Cynips Burgundus, or a species affecting the terminal buds almost similarly, with distorted form of mixed

buds and stipule-like growths, afforded a good many specimens in one locality from some felled trees.

Dryophanta divisa (?) gave a few of its roundish leaf-galls, and of *Neuroterus* there was a good supply of the species *N. Malpighii*, producing the common "leaf spangle." Of *N. ostrens*, producing the small round gall from the leaf-veins, protected in its early stages by a scale or two, bearing a fanciful resemblance to an oyster-shell, there were only a very few stunted and unhealthy specimens of growths on one or two leaves.

Taken together these give fifteen species, to which possibly a few might be added (still undetermined from peculiarities of development, or requiring the insect also to distinguish them from others resembling them in form); probably, also, there are several other species not observed yet which another season's observation may show, as several of the common kinds are missing from the list, and more especially some of those requiring the damp surroundings chiefly to be found in the thick woods either not existing, or practically closed for research in such near neighbourhoods to London.

In the Gloucestershire district, on the contrary, the moisture of the air between the Severn and Wye near their confluence, with the peculiarly thick under-growths of the Oak woods of those parts (where Hazel and coppice, mixed with Bramble and climbing plants, often form a mass impenetrable without the help of a bill-hook) and also the quantity of herbage which in completely rural districts may be left untouched in nooks and stray patches (very differently from what must necessarily be the case in the vicinity of London), are all favourable to the growth of moisture-loving galls. Of the species present near Isleworth only the galls of *Cynips ferruginea*, nodule, and *Burgundus* (all of them affecting parts of the tree well-exposed to the air) were absent in Gloucestershire, whilst on the other hand the galls of *Andricus infiator*, *Biorhyza aptera*, *Trigonaspis megaptera*, *Spathegaster tricolor*, and the large (frequently found) rosy or green round gall of *Cynips folii*, found on the leaves in autumn, all (as far as this season's observations go) missing near Isleworth, were well represented in the district near Chepstow.

Of these the gall of *A. infiator* (which appears merely like a shoot whose growth has been stunted into a sort of barrel-shaped lump beset with buds), is to be found only, as far as I am aware, on the upper shoots of the Oak, and the *B. aptera* (of irregular shaped knobs of various sizes), being subterranean in its growth on the root fibres, can only occasionally be met with, but the round pink or light coloured leaf gall of *Spathegaster tricolor*, noticeable from the long feeble hairs scattered over the surface, only occurred in damp coppices or on spray overhanging ditches; and the rosy-tinted gall of *T. megaptera* might be found year after year half buried in moss, growing almost at the ground level on the bark of Oaks by a wood-road often almost an impassable slough.

Other galls appeared also especially to flourish in damp situations; the marble galls grew with a luxuriance I have never seen equalled except in a locality where the bush bearing them was immediately above a stream, the galls covered by leaves; and the *A. radicis* also thrived remarkably and attained a good size on the Oak roots spreading amongst grass or in damp stagnant situations. The single-celled form of gall of this insect (*A. radicis*) was still more plentiful in the district, sometimes appearing with the compound one on the rough bark of the roots just free of the ground but chiefly in any new growth of bark. Where an arm had been lopped or bark injured by accident these single-celled galls might be found (looking like a tooth with convex top and a single fang) well buried in the soft growths, and in older bark the perforations on the surface showing the broken top of the cells after the escape of the insect) were innumerable, sometimes extending for several feet along an injured bough or the bark of an exposed root.

Of what I believe to be the rare gall of the *Aphithrix corticis* I once found a few specimens growing on the bark of an Oak just above the ground level, but the insect not being procurable I could only judge by the peculiar form of the gall itself.

A few other species of galls also existed in the district, and several peculiar growths which (from subsequent observation) might, I believe, have proved in the hands of those well versed in the subject to be galls of some of the rarer species, but from the limited means of ascertaining the names of the various kinds

that I then possessed some of these escaped me, and the most interesting still remain to be determined, if possible, by rearing from a similar gall found in the neighbourhood of Isleworth. O.

LOVE'S MOSS DRAINER.

A PUBLIC trial of Love's Moss Draining Machine took place a few days ago on Chat Moss, in the presence of a large number of gentlemen especially interested in the draining of bog and moss land. The weather was extremely favourable for the trial. The following is a description of the work performed:—The length of drains excavated was 150 yards each, which was performed in seven and a-half minutes, and the raising up, running back idle, and lowering again into work took four and a-half minutes, making a total of twelve minutes for excavating a drain 150 yards long, being at the rate of 3 miles per day of eight working hours. The drains were cut out at 32 inches below the surface. The bore or tunnel was intended to be 8 inches in diameter, but was only a little above 5 inches, owing to the fact of the excavating auger being driven at too low a speed for the progress of the machine, and which can be deepened as the speed is increased. The material excavated is forced up through the body of the machine in a continuous stream of fine pulp 2 inches deep and 13 inches wide, and the slit made by the machine closes in so neatly that the line of drain could scarcely be traced were it not for the line of pulp left along the surface. Specimens of the pulp dried into fuel, that were cast in a mould 8 by 5 by 3 inches, equal to 120 cubic inches, when quite air-dried were only $4\frac{1}{2}$ by $2\frac{1}{2}$ by $1\frac{1}{2}$ inches, equal to $14\frac{1}{2}$ cubic inches, showing a shrinkage of $87\frac{1}{2}$ per cent. The loss in weight by the evaporation of water was 85 per cent. This dense peat weighs 57 lb. per cubic foot, and is as hard as coal. This fact would demonstrate that the 32 feet in depth, which this part of Chat Moss is, would yield 4 feet deep of this dense fuel, or above 4350 tons per acre. This moss when dried in its normal state shrinks only 36 per cent., and weighs 13 lb. per cubic foot of peat. During the operations attention was directed to the decrease occasionally caused by the slipping of the driving rope, not having grip enough, through the pulley being only 2 feet in diameter. Wherever these slips occur the tunnel is imperfect. A drain was opened to show the defects arising from these slips of the driving rope, and from the auger running too slow for the progress of the machine. The present speed is 850 revolutions per minute. This will be increased to 1500, and the progress of the machine reduced so as to double the present excavating power. The power used was Hornsby's 8-horse power portable engine, 1500 yards of Manila rope, and two windlasses, with 300 yards each of $\frac{1}{2}$ -inch diameter steel wire rope. The distance from the engine when the machine was at the starting point was 900 yards, and the pressure of steam was never above 60 lb. The difference caused by increased depth is only about half-a-horse power per foot; the excavations having to be raised the same height whether the depth be $4\frac{1}{2}$ feet or any less depth, the power required to drive the excavating and elevating gear are always the same. The principle of the machine was pronounced a success, which the rearrangement of some of its details would render complete.

THE CULTIVATION OF THE ROSE.*

(Concluded from p. 427.)

SOIL AND SITUATION.

It is generally agreed by growers that a strong, stiff loam is the most suitable for successful Rose cultivation. Such a soil, resting on a well-drained foundation, the Rose perfectly luxuriates in, if other essential wants are at the same time supplied, the chief requirement being a genial situation—that is, a sunny opening, if possible, sloping gently to the south, protected from winds and draughts from all quarters—in short, neither windy nor shaded, neither dry above nor damp below. A proper situation is of more importance than manures, soil, or anything else required. To prove this assertion, I may mention what I have been a witness to in various parts of the country. First, the old favourite Rose Cloth of Gold is well-known to be difficult to flower satisfactorily,

even where other tender Roses do very well. Some years ago I saw Cloth of Gold hiding a large portion of a south wall with its glorious massive blossoms, in a garden called Clotfolach, in Strath Tay; such a sight I never saw before or since produced by this noble Rose. The soil all along Strath Tay is remarkably light, consisting of rotten rock in the main, showing alluvial deposit to some extent, and a large proportion of sand, intermixed with shining mica. Contrasting with the inland situation of this strath, and very much in its climate, I shall next instance Sutherlandshire. At Golspie, near Dunrobin Castle, the Rose prospers amazingly. Here, with the sea close at hand, may be found the most splendid examples of our popular H.P. and Teas in particular. Every nook and corner about Golspie has its Rose blossoms in profusion. One plant in particular I noted—a Gloire de Dijon, trained on a house-front measuring 21 feet by 20, a space completely covered by well trained growths, which were one mass of most magnificent blossoms from top to bottom. There must have been many hundreds of open and half-open blossoms on it when I saw it. In the gardens of Dunrobin the Roses were almost as beautiful as the fountain basins of *Nymphaea alba*, which leave their impression on the memory of every visitor when seen in flower. The soil in this district is of a comparatively light nature, being much mixed up with sand and large particles of grey granite.

PREPARATION OF THE GROUND.

Supposing one is about to prepare a bed or border for Roses where the soil happens to be "stiffish loam," we think it would be bad judgment to apply as manure any compound of an adhesive description; for such soil the manure ought to have a contrary tendency, and at the same time unite the necessary stimulating element—such substances as stable-manure, sand, leaf-mould, and lime rubbish incorporated, and allowed to remain for some months before using. On the other hand, for soil naturally poor and light, the compound may be composed of cow-dung, old night-soil, and fresh stiff loam containing as much fibre as possible. These, with a liberal supply of urine laid in a heap for a time, make a splendid manure for Roses when grown on light ground. In any soil the Rose is a greedy feeder, and demands annual manuring.

In making a Rose garden, if the subsoil be at all stiff and retentive of water, it ought first to be properly drained, conveying the water to some distance by a main drain. Should the subsoil be sandy and gravelly, and drainage already exist—unless, as sometimes happen, springs exist which require to be drawn off artificially, and thus prevented from over-sopping the soil, in which case after draining and allowing time to draw off the superfluous damp—the ground may be well trenched, depositing at the bottom of the trench a good store of prepared compost, besides mixing the overlying body of soil with goodly portions of the same material; as the trenching process goes on, heap the surface into deep rough ridges, and leave it in that state all the winter, that it may be properly pulverised by the united action of frost, wind, and rain. Again, in March previous to planting let the ground be partially trenched, after a top-dressing of wood-ashes or burned clay should it be adhesive. Top-dress the light soil with the compost recommended as a suitable manure for its kind. The ground is now in readiness to receive the plants. Planting may be proceeded with; and as to the distance to place one plant from the other in the rows that depends much upon the vigour or delicate nature of the respective kinds—some require 15 or less inches between, others as much as 3 feet. The habit of the plant should be understood as nearly as possible before its situation in the bed is fixed.

PRUNING.

I believe most of us have much to learn as regards pruning Roses, scarcely a dozen kinds are alike in vigour or require the same amount of pruning. Out of a collection some are improved by close pruning, others flourish best with scarcely any. The rule ought to be to cut weak growers more closely back than vigorous ones; for instance, Tea Roses, Bourbons, Chinese, and Noisettes, all suffer by too close pruning; and, on the other hand, many of the Hybrid Perpetuals are improved by close pruning. By practice alone we can judge how best to use the knife; however, this ought at all times to be conducted with an eye to the regularity of form and the natural habit of the variety acted upon.

The proper time to prune is rather a disputed subject. Some prefer the autumn, but I think the majority—and rightly, too—advocate spring pruning. In ordinary seasons I consider the beginning of March quite soon enough, and, indeed, too soon in such a season as this. The Rose suffers much by late spring frosts, and even the blighting winds of early spring when there is no frost. Further, regarding late pruning, a number of years ago, when I was in the Highlands, I had in charge a number of very old, large, and fine standard Roses studding the flower garden. Unfortunately, the season of Roses was always past before the family came there to reside. Those standards were pruned back somewhat in early March along with the early Roses, and all commenced an early and rapid growth, which induced me to experiment a bit. With the object of having those standards come into bloom in the middle of August, instead of July, I had them all pruned back to dormant eyes in the hard wood in the latter end of April. For some time succeeding they looked very scrubby beside those at their feet covered with promising shoots, but, ultimately, I was well repaid for my experiment, for we had quantities of grand Roses in August and September that year from these giant standard heads.

DISBUDDING.

This is most important if pursued systematically both in the blooms and wood-buds, which in the latter in no small degree obviates the removal of what would subsequently form hurtful growth. Disbudding ought to be conducted with an eye to a symmetrical outline in the plant, thinning out all that are likely to prove useless, and preventing the free action of air and light throughout the body of the plant, which is essential to health, cleanliness, and proper ripening of the wood. Very rank growths ought to be removed when first discovered amongst others, seeing their tendency is to rob them of their share of sap, making them thin and weak, if not worthless, besides spoiling order and regularity of plant.

Pegging down the shoots of dwarf Roses, more especially when growing on their own roots, is a vast improvement to the usual mode of conducting growth. This I experienced some years ago. For the sake of experiment I had a large bed, which centred a portion of a flower garden, planted with sixty of our most popular H.P.'s and some of the hardiest Tea Rose. This bed was trenched 4 feet deep early in March, and highly enriched by turf and stable manure; indeed, in a similar way to that in which one would prepare soil for bench potting. The Roses were then and there planted partially on their sides, the more to facilitate the layering; very little was taken from the length of the previous year's growth, a mulching of short horse manure was spread over the bed, and the shoots were pegged down over the dressing, distributing the growths in such a way as to insure the most regularity over the bed. In all respects this resulted in a perfect success, the Roses were both abundant and good, indeed some of them prize-winners, and the bed was entirely covered with young growth. In the March following the required shoots were layered, and what were not wanted were cut clean away without attempting spurring on that bed.

INSECTS AND MILDEW.

These are very destructive, at times defying all our efforts to exterminate them without sacrificing the plants also. Soapsuds form, perhaps, the best remedy against insects and mildew. I have found a constant application of soft-soap dissolved in water (at the rate of a piece of soap the size of a hen's egg to a 3-gallon can of water) act effectually and prove beneficial to the growth of the plants. This I have experienced with pot Roses in particular.

In monstrous growths in Roses, the pistils are developed into leaves in some instances, and in others Rose petals, along with imperfect buds of Roses clustered into a confused mass. The stamens invariably retain their natural character, or are transformed into flower-petals. This is the effect or result of some influence difficult to understand, which it should be our purpose to discover, and, if possible, prevent. In my opinion, the cause of these monstrosities is attributable to the roots being placed on a cold, damp bottom. The plant is excited into growth by the returning heat in the atmosphere after a lengthened state of inactivity; therefore, its tendency is to grow, but the absence of sufficient sunlight and heat prevents the perfect elaboration of its sap.

* Read at a Meeting of the Scottish Horticultural Association, by Mr. A. Kerr.

I am informed by a gentleman, Mr. Scott, of Philadelphia, who has been an extensive cultivator of the Rose, both in and out-doors, for the Philadelphia market for the past thirty years, that he never once saw a green-centred Rose in America during all those years; and he was astonished, on visiting this country this summer, to witness so many existing amongst the very Roses he has been accustomed to grow in America. One thing I feel convinced of—that is, although America is subject to rigorous frosts and long winters, that country has likewise the advantage in heat over a great portion of the year, the effect of which on the Rose will be to ripen root and branch to perfection prior to the occurrence of frost. Further, an American spring is very different to ours—no periods of alternate warmth and biting winds and rains. Spring opens there with sharp frosts at night, but the days are bright and warm, and thus spring grows into summer without alternate checks to vegetation.

I have already entered at some length into the mode of striking cuttings from ripe shoots; let us note what may be accomplished by means of cuttings while they are yet green. These are in a more active state of growth, and when properly handled root quickly, but they must be put into bottom-heat and kept rather moist at the root. These half-ripened shoots are prepared for insertion in a similar manner to other Rose cuttings. Pans or pots should be used to root them in, and the soil may be composed of two parts light loam, two parts sand, and one part leaf-mould, not too much reduced by age. The cuttings are inserted at regular distances around the edge of the pots, then the central portion filled with the tallest of the cuttings. After pressing the soil firmly to them the operation is completed by scattering a handful of sand amongst the cuttings. Store them away in a shaded corner in a cool house, placing a bell-glass over each pot to prevent the waste of moisture from the soil, and at the same time to exclude air. Allow them to continue thus situated for about three weeks, by which time they will be in a proper state to be put into heat to root.

I have practised another method with fair success. This applies to prunings taken from old forced Roses in November. These prunings were treated exactly similar to those last described; but, instead of being put under glasses, they were shelved into an intermediate house used for bulb forcing, and stood facing the sun until the succeeding spring, when that aspect became too hot for them, and necessitated their removal to cooler quarters. A number of these cuttings bore moderately large blossoms in the latter end of the succeeding summer, so well did that plan succeed.

NOTES ON SOUTH-EAST AFRICAN VEGETATION.*

WHEN travelling in a strange country, totally free from the biasing opinions of fellow beings, and dwelling continually with Nature herself, we have the opportunity of comparing the country as it really exists, with the imaginary one brought into existence through the perusal of works by descriptive writers, travellers, &c. Without intending to cast a slur on any fellow wanderer, there is not the least doubt that travellers, after having left the country of their sojourn, and returned to the land of their birth, often fall into the error of improving the bright side of what they beheld, and lessening the drawbacks and difficulties of the country through which they travelled. No doubt this is owing to the natural buoyancy of men's minds, and to the fact that whilst past pleasures increase in brightness, bygone troubles lose nearly all their terrors. As a rule, with few exceptions, I have been disappointed in my preconceived ideas of countries, and, judging from fellow travellers with whom I have come in contact in this country, I am not the only victim to lofty imaginations. The luxuriantly clad island of Ceylon, the teeming valleys of Sikkim, the majestic snow-clad peaks of the Himalayas, the island-studded and extensive harbour of Port Jackson, the Fern valleys of Illawara and a few other places, not only came up to my preconceived notions, but far surpassed all expectations. Still, on the whole, disappointment has been my lot, and especially with Natal and the Transvaal.

On looking at an enlarged map of S.E. Africa, and taking into consideration the numerous rivers and

mountains, the latitude and altitude, the mind would at once, independently of descriptive books, picture in imagination a country with the valleys and river banks clad with forest and bush, and the grassy plains inhabited more or less by all sorts of African game—a country exceedingly fertile, not possessing the impenetrable jungle and forest of India and South America, but resembling to a certain extent Australia, with its grassy plains and continual belts of timber. But, alas! in spite of the glorious accounts given of Natal and the Transvaal, it is not so. After leaving the coast land it is possible to travel on to Leydenburg, a distance of over 500 miles, without seeing a plant worthy of the name "tree;" and from the frontier of Natal to Leydenburg it is possible not to see a bush. Of course a few introduced plants, as Eucalyptus globulus, fruit trees, &c., are not included in these remarks. And as for game, the whole distance can be travelled without seeing a four-footed beast, except at Lake Chrissie, in New Scotland. Undulating hills and extensive plains, covered with coarse grass, and made beautiful with the gorgeous blossoms of innumerable bulbs, often relieved by lovely herbaceous and diminutive plants, are the natural features of the highlands of S.E. Africa; forest and bush, which nearly always consists of Acacia, being the exception. The fact that the Transvaal, Free State, and Natal (except the coast lands), are devoid, as a rule, of arborescent and fruticose growth, is to me perplexing and unaccountable. The alluvial is rich and often deep, water is plentiful, altitude various, latitude suitable; in fact, all that is required, as far as my present knowledge goes, to develop and sustain the higher organisms of the vegetable kingdom.

The country from Durban to Newcastle, as seen from the main road, consists of a series of undulations, varied here and there by small and picturesque plateaux of slight elevation, which give to various parts a broken and rough aspect. The plateaux and hillsides are for the most part covered with a superficial conglomerate layer, often containing immense boulders, which although useful for building cattle kraals, walls and houses, greatly add to the drawbacks of agriculture. Fuel is scarce, and dried cowdung is generally used as a substitute. Rivers are numerous, and the whole country well supplied with water. In the uplands of Natal these rivers can be profitably utilised for irrigation purposes by bringing them over races and shoots, as they are very rapid, and have considerable fall. At Newcastle a vast amount of coal has been discovered, but owing to the difficulties of transport and want of railways it is of but little utility at present. The coal is wonderfully light, and produces a very white ash; it does not seem to possess sufficient body in it to be used for locomotive purposes.

In crossing the Drakensberg mountains from Newcastle to the Sandpruit River in the Transvaal, the country is indeed rough, with plenty of beautiful mountain scenery, but destitute of that which gives a charm to all scenes—forest and bush. To the weary traveller any change is welcome, and so it was with us. After the treeless and bushless hills of Natal we felt a slight relief in winding our weary way across the broken and grassy plains of the Transvaal, anxiously looking out for vegetation, but always disappointed. A rolling plain, a precipitous plateau, and winding rivers, with uninterrupted views, certainly possess an amount of beauty, but when the same class of scenery is traversed for hundreds of miles without a bush to enliven the prospect, it becomes monotonous and gloomy to the lover of forest shade. After leaving the rising town of Leydenburg and moving to the North, the welcome sight of trees broke on our view. At first they were small, scraggy, and scattered, afterwards, as we journeyed to the northwards, they became larger, and then we beheld the ravines and gullies teeming with innumerable shrubs, climbers, and Ferns. The scenery on these mountains, known here as the Hooge Veld Range, is truly grand and imposing, possessing all that is requisite for the location of man, and the production of European crops and fruits. The altitude of several peaks is over 7000 feet above the level of the sea, the sides sloping down into deep ravines and broad fertile valleys, all traversed by well supplied creeks and rivers. The Speckboom, Blyde, Crocodile, and Sabia Rivers, are the principal watercourses in this district, all which eventually empty into the Indian Ocean at Delagoa Bay, which is S.E. from here.

The Transvaal is undoubtedly a valuable acquisition to the British Empire, especially as regards its mineral wealth; but as a colony for the settlement of agricul-

turists I should certainly rank it as one of the last places in the British colonies. The difficulties of exporting produce, in possessing no seaboard and no means of inland transport, the scarcity of timber, want of fuel, uncertainty of demand, horse sickness, cattle disease, and extreme climatic tendencies, all tend to the non-development of agriculture in the Transvaal. It some districts it is certain death to horses during the summer months. Losing three horses myself through this horrible sickness, I took an interest in finding out the why and wherefore of the disease. Every night, and especially towards morning, a dense mist, combined with an obnoxious miasma arising from the ground, covers the hillsides and fills the valleys; this mist literally soaks the scanty vegetation, so much so that it takes several hours of the sun's absorbing rays to restore it to its proper nature. I was given to understand by old and experienced travellers that if I prevented the horses from partaking of this dew-besodden herbage in all probability they would escape the fatal sickness; I therefore took the precaution to fasten them to the wheels of my cart every night on camping, and not to allow them to feed until the sun had banished the dew from the grass; but alas! all was in vain, for one by one they all fell victims to the disease. Through this I came to the conclusion that the disease was generated by inhaling the obnoxious miasma, and not through eating the damp herbage. Stabling the horses every evening has been partly successful, but even there the miasma carries its deadly effects. Donkeys are proof against this malady; in fact they are proof against all the various diseases of S.E. Africa, except the "tsetse" fly, whose bite is fatal to all domestic animals. Eight days after the horse has become infected by the miasma malady, rapid breathing and extended heaving of the sides, with running at the nostrils, and swollen head sets in, and after a few hours of excruciating agony the poor brute dies.

The part of the Transvaal through which I travelled on reaching this spot from Leydenburg is as lovely a country as man would wish to settle in; cattle and sheep thrive admirably, temperate and subtropical fruits, tobacco, and all European crops would flourish in abundance, timber is plentiful, no lack of water, and no doubt an abundance of mineral wealth, for in this district the goldfields of South Africa exist. The only drawback being as to how the produce is to reach the seaports, and how the imports—sugar, tea, clothing, &c.—are to reach the settler. The present means of transport are by oxen and waggons to Durban, over 600 miles, which, of course, takes away the profits of the cultivator, and brings to a fabulous price the imported articles of consumption. It is only 150 miles from Leydenburg to Delagoa Bay, but the fever and "tsetse" fly prevent transport in that direction.

The fever and "tsetse" fly appear to go hand-in-hand, in fact to be the effects of the same cause, and have up to the present time prevented the rich jungles of the coastland north of Delagoa Bay from being explored, especially botanically. The fly prevents all means of transport by animals, and the fever for eight months out of twelve debars the European the pleasure of traversing the swampy forests during the time when Nature displays her floral beauties. From November to June it is almost certain death to descend into the lowlands towards Inhambane, Delagoa Bay, and St. Lucia Bay. The range of the "tsetse" fly commences north of St. Lucia's Lake in the Amatonga country, runs N.W. and crosses the Umzuti River to the foot of the Loobombo Mountains, skirting the foot of these mountains, north to the Sabia River, then in a N.W. direction to the Olifant River, and on to the Limpopo River, keeps to the south of this river as far up as the 28° E. longitude, crosses the river and comes back for a considerable distance on the north side, eventually striking north to the valley of the Zambesi River. Within these limits the domestic animals cease to live, and as a rule they form the boundary line of the fever-stricken district. *Chris. Mudd.*

THE WOOLHOPE MENU.

FOR such of our readers as may not be so deeply versed in fungi as we the members of the Woolhope Club, we append a brief explanation of the allusions to be found in the pictorial border of the menu card. Beginning at the top, the pleasant faces seen in the "edible" fungi, and the dolorous mementos manifest in the "poisonous" ones, explain themselves. The former are suitable for frying, and "Fries" is the greatest living authority on fungi; the latter cause unpleasant symptoms and pain us—"Panus" is a genus of fungi; the pill-box, pill and medicine-bottle, are represented by the genus of fungi named

* Communicated by Messrs Veitch & Sons, of Chelsea.

"Pilobolus." Mr. Berkeley in the top centre is being attacked by a starry Puff-ball (a species of vegetable octopus), and his exclamation of affright naturally takes the form of another genus of fungi named "Odontia." It will be observed that Mr. Berkeley, who is applying "Salus" to the nose of the monster (a material "no fungus can withstand") has let fall his *Outlines of Fun-gology*. The bottle of "Currey" on the left immortalises Mr. Fredk. Currey, the famous fungologist. "Kneiffia" underneath is a genus of fungi, and "Forkia" is a genus shortly to be established. The cuneiform inscription indicates the character of the fungoid octopus and the Colorado beetle at Hereford. The porcine quadruped on the left points to Dr. Robert Hogg, who has published a

time to the "veal" which at an early period clothes the bones of all oxen. "Magnus" refers to Dr. Magnus, of Berlin, the fungologist. The greatness of this author's name has expelled the cork from the bottle. "Bad-ham," on the dried pig's leg, refers to Dr. Badham, who wrote the *Excellent Funguses of England*; whilst the mole hanging head downwards indicates the miserable condition of Mr. Lee's "molar theory," which referred the formation of fairy rings to the underground gyrations of the mole. "Hygrophorus" (the Water Bearer) is the name of a large genus of watery fungi; and the "Myxomycetes" are a large group of fungi, now attracting peculiar attention. Phallus is a genus of fungi, which does service here in indicating that there is "no fallacy" as to the

genus of the same class of plants. C.E.B., M.A. on the hussy's weapon, point to the name and degree of Mr. Broome, the fungologist. "Sparassis" is an important genus of fungi, which is here giving a hint to the combatants as to how to proceed when their artificial weapons are no longer available. "Crucibulum" is the name of a large genus of fungi, and means a saucapan: the "Batch" inside is the name of a great fungus author. "Flammula"—a little flame—is a subgenus of fungi; and "Fries Epi-crisis" (the fat-in-the-fire) is the name of the best text-book of fungi in existence. The nature of the Woolhope ketchup, or "cats-up," was fully described in the *Gardeners' Chronicle* last year. As a matter of fact the word "Poisons" (fish) was misprinted "Poisons" by the printer; it was also overlooked by the revising editor, and appeared as "Poisons" on all the cards on the fungus dinner-table.

FIG. 90.—THE WOOLHOPE CLUB MENU.

book on fungi, and the inscription "Non Sow!" indicates that he is not to be confounded with Sowerby. The umbrella handle and great knife on the left always appear at the Hereford meetings: they belong to Mr. Plowright, the famous surgeon and fungologist of King's Lynn. The wine bottle bears the name of the renowned wine merchants of Rood Lane, who supply so many fungus eaters with their (as pronounced after dinner) "Sphæria champign." Sphæria is an immense genus of fungi, and "champign" is Champignon with its tail off. On the right we have Dr. Bull, the physician of Hereford, supporting "Cornu" (Latin for Dr. Bull's Horn of Plenty). M. Max Cornu, of Paris, is one of the highest living authorities on fungi, and was a guest at Hereford. The chains and ropes ornamenting the bovine nose indicate the power and irrepressible energy of Dr. Bull. Leveille is the name of a great fungus author, and refers at the same

quality of the wine consumed. Some fungi bear spiral cork-screw-like springs for use in dispersing the spores; the springs are named "elaters," therefore the cork-screw figured is in more senses than one an "elator." The bottle of cider on the left and Agaricus cidaris are synonymous, and "Du-Port" on the right is the name of an excellent fungoid clergyman from Norfolk who attended the Hereford meeting. Arriving now at the bottom we have "Tode," a writer on Mushrooms, together with a figure of Boletus edulis beheaded. Hussey, Broome, Cooke and Curtis are all renowned fungologists—Hussey and Cooke are in conflict, the latter has just thrown a rolling-pin (Clavaria—a genus of fungi) at the latter, and is now in the act of discharging a basin of batter (Batarrea—another genus of fungi) at her opponent. The cook's name is Psalliotia, a sub-genus of fungi, the hussy's name Polyporus, a

ON THE SEDUMS OF THE RUPESTRE GROUP.

(Concluded from p. 307.)

4. *S. reflexum*, Linn. Sp. Plant., edit. ii., p. 618; Smith, Engl. Bot., t. 695; 3 edit., t. 804; Engl. Flora, vol. ii., p. 320; Gren. and Godr. Fl. Franc., vol. i., p. 626; Koch, Synop. Germ., edit. ii., p. 228; *S. rupestre*, D.C., Plantae Grasses, t. 115; Reich. Fl. Excurs., No. 3546, in part.—Densely tufted. Stems trailing at the base, $\frac{1}{2}$ inch thick, producing copious sterile leafy branches 2—4 inches long, which bear at the top oblong rosettes of leaves 1 inch in diameter. Leaves glaucous, subulate, terete, mucronate, the outer ones spreading, $\frac{1}{2}$ — $\frac{3}{4}$ inch long, $\frac{1}{2}$ inch broad, rounded on both faces and as thick as broad, arranged in six rows. Flowering stems $\frac{1}{2}$ — $\frac{3}{4}$ foot high, bearing about 20 erecto-patent stouter leaves, which are distinctly spurred at the base, the lower ones $\frac{3}{4}$ inch long, $\frac{1}{2}$ inch broad, $\frac{1}{2}$ inch thick. Cymes dense-flowered, 2—3 inches in diameter, composed of about four dichotomously-forked scorpioid branches; lower flowers shortly pedicellate, upper sessile. Calyx glaucous, campanulate, $\frac{1}{2}$ inch in diameter, $\frac{1}{2}$ inch long; segments oblong-deltoid, twice as long as the tube, hollowed out rather in the centre. Expanded golden-yellow corolla $\frac{3}{4}$ inch in diameter; petals 5—7, lanceolate, $\frac{1}{2}$ inch long, channelled down the face. Filaments golden-yellow, nearly as long as the petals, pubescent at the base; anthers oblong, minute. Carpels as long as the filaments, narrowed gradually into a style nearly $\frac{1}{2}$ inch long.

The above description is taken from the large stout long-cultivated form of reflexum which one sees everywhere upon old thatched roofs and in cottage gardens, the plant figured as reflexum in English Botany and as rupestre by Redouté and De Candolle. There are numerous varieties of what I look upon as the same species in cultivation, of which the following are the principal. In characterising them I have been mainly guided by a set of unpublished coloured figures in the Kew collection of drawings which were made from specimens which flowered in Kew Gardens in the year 1828.

1. *S. collinum*, Willd. Enum. Hort. Berol. Suppl., p. 25, Wimm. and Grab. Fl. Siles., vol. i., p. 444. This is the robust bright-flowered form just described, the reflexum described by Willdenow in the place cited being *S. virens*. The *S. collinum* of Haworth differs from this by its pale yellow flowers.

2. *S. virens*, Willd. Sp. Plant, vol. ii., p. 764; Haworth, Syn. Succ., p. 116.—Rosettes 1 inch in diameter. Leaves not at all glaucous, but bright green from the beginning, $\frac{1}{2}$ — $\frac{3}{4}$ inch long. Flowers as large as in collinum, bright yellow.

With us at Kew this maintains its bright green colour from year to year, grown side by side on the rockery with collinum and albescens. On the subject of the value of colour as a distinctive character in the plants of this group, those interested in the matter should read a paper by Grenier in the tenth volume of the *Bulletin of the Botanical Society of France*, pp. 253 to 257. This form is the *S. reflexum* of many authors, as Willd. *Enum. Hort. Berol.*, p. 25, Reich. *Flora Excursoria*, No. 3545, and *Te. Crit.*, tab. 276, fig. 459, and Lloyd, *Flore de l'Ouest de France*, p. 177. An allied or identical form sent to Kew under the name of *S. Bourceti* I have not seen yet in flower.

3. *S. albescens*, Haworth, Revis. Succ., p. 28; D.C. Prodr., vol. iii., p. 407; Gren. Fl. France, vol. i., p. 627; *S. glaucum*, Smith, Eng. Bot., tab. 2177; Engl. Flora, vol. ii., p. 321, not Waldst. and Kit.—A less robust form than collinum, with very glaucous leaves, the largest of those of the sterile rosette about $\frac{1}{2}$ inch long, and 1 line

in breadth and thickness, the dense cymes 1-2 inches broad, the nearly white calyx $\frac{1}{2}$ inch long, and the bright yellow corolla when expanded $\frac{1}{2}$ inch in diameter.

This is the commonest wild form of the plant, indigenous in England on dry banks at Mildenhall, in Suffolk, whence it was sent by Mr. Eagle for the *English Botany* figure, and on rocks at Babbicombe, near Torquay. It is the plant figured as rupestris by Redouté in De Candolle's *Plantes Grasses*, tab. 116, and it is the wild Swedish plant which was called rupestris by Linæus, and which is distributed under that name by Fries in his *Herbarium Normale*.

4. *S. minus*, Haworth; *S. reflexum*, Fl. Dan., t. 113.—The most slender variety of all, with small sterile rosettes, not more than $\frac{1}{2}$ inch in diameter, glaucous leaves and bright yellow flowers not larger than those of rupestris.

5. *S. recurvatum*, Willd. Pl. Hort. Berol. Suppl., p. 25; Haworth, Rev. Succ., p. 28.—A dwarf form, near albescens with glaucous leaves and bright yellow flowers, the lower leaves of the rosettes recurved.

6. *S. septangulare*, Haworth, Syn. Succ., p. 116.—A form near albescens, with glaucous leaves, $\frac{1}{2}$ inch long, in seven distinct rows, the outer ones of the rosette spreading and straight, bright yellow flowers in cymes 1-1 $\frac{1}{2}$ inch broad.

Of this form we have lately received characteristic specimens from Mr. Ware.

7. *S. vivescens*, Willd. Enum. Hort. Berol. Suppl., p. 25; Haworth, Revis. Succ., p. 29.—Habit and glaucous leaves of var. albescens, but petals pale sulphur-yellow.

Of this we have wild specimens in the Kew herbarium gathered by Desmoulin in the Pyrenees, on the Butte St. Justin near Barèges, at an elevation of 3500 feet. Haworth notices also a similar form with green leaves, which I have not seen.

8. *S. cristatum*, Schrad. Hort. Goett., tab. 10; *S. portlandicum*, Lobel, Icon. 380; *S. crassicaule* and *monstrosum*, Hort.—This is not a proper variety, but a monstrosity, with dilated, flattened, sterile shoots, thickly beset with reduced leaves about $\frac{1}{4}$ inch long.

Taking *S. reflexum* as a whole, it has been cultivated so much and so long, that it is difficult to ascertain its indigenous range. It is clearly a native of France, Italy, Germany, England, and Sweden. Willkomm and Lange can adduce no certain evidence for it in Spain, where rupestris abounds; but certainly northward, and probably also eastward, it overpasses the geographical bounds of that species; and these seem to be the only two out of the five European kinds that are wild in Central and Northern Europe, decidedly beyond the northern bounds of the Mediterranean region.

5. *S. anopetalum*, D.C., Fl. France, vol. vi., p. 526; Prodr., vol. iii., p. 408; Mem. Crassul., t. 8; Reich. Ic. Crit., vol. iii., tab. 266; Gren. Fl. France, vol. 1, p. 627; Willk. and Lange, Prodr. Hisp., vol. iii., p. 137; *S. hispanicum*, D.C., Fl. France, vol. iv., p. 395, non Linn.; *S. rupestris*, Vill. Delph., vol. iii., p. 679, non Linn.—Densely tufted. Barren shoots bearing at the end oblong rosettes of leaves, 2-3 inches long, about 1 inch in diameter. Leaves of the rosette arranged in about six rows, terete, glaucous, or green, the outer ones $\frac{1}{2}$ inch long, 1 line broad, $\frac{1}{4}$ inch thick, rounded on both face and back. Flowering stems $\frac{1}{2}$ foot high, bearing 20-30 erect, stouter leaves. Cymes dense, 1-2 inches across, consisting of 3-4 forked scorpioid branches, all the flowers sessile. Parts of the flower usually in sixes. Calyx $\frac{1}{2}$ inch in diameter, $\frac{1}{2}$ - $\frac{3}{4}$ inch long, the erect lanceolate segments 3-4 times the length of the short campanulate tube. Petals linear, erect, pale yellow, half as long again as the calyx, never spreading widely. Filaments rather shorter than the petals; anthers minute, oblong. Carpels greenish, $\frac{1}{4}$ inch long, narrowed gradually into an erect style, half as long as the ovary.

This flowers early in July, at the same time as rupestris, and before reflexum and ochroleucum. It is wild in Spain, Italy, Switzerland, and the southern half of France, and extends eastward to Turkey and Asia Minor. I cannot distinguish it from *S. reflexum* without flowers, but in the flowering state it may be recognised at a glance by the character given in the key. The sheet in Sir J. E. Smith's herbarium labelled "*S. reflexum*, Fl. Brit.," contains specimens of this species, but it has no claims to be regarded as British. *S. Verloti*, Jordan, in *Bull. Bot. Soc. France*, vol. vi., p. 606, is a slender variety with green leaves. *S. aristatum* of Villars is probably a dwarf form either of anopetalum or reflexum, but the plant seems to be quite unknown to recent French botanists.

6. *S. amplexicaule*, D.C., Rapp., ii., p. 80; Fl. France, vol. v., p. 526; Gren., Fl. France, vol. i., p. 628; Willk. and Lange, Prodr. Hisp., vol. iii., p. 136; *Sempervivum tenuifolium*, Sibth., and Sm., Prodr. Fl. Græc., vol. i., p. 355; *Sempervivum anomalum*, Lagast, Nov. Gen., p. 17; *Sedum rupestris*, Linn. Herb.; *S. rostratum*, Tenore, Fl. Neap. Prodr., p. 26.—Densely tufted. Stems slender, wiry, under 1 line thick; sterile decumbent branches 1-3 inches long, bearing at the top rosettes 1-1 $\frac{1}{2}$ inch long of slender subulate ascending or squarrose leaves $\frac{1}{2}$ - $\frac{3}{4}$ inch long, the lower half or third of which is dilated into a grey cartaceous membrane, by which they clasp the stem. Flowering stems not more than $\frac{1}{2}$ a foot high, very slender, and wiry, bearing a few distant ascending linear leaves, not dilated like those of the rosettes into a broad clasping base. Cymes very lax, sometimes reduced down to a single flower, at most consisting of two or three distantly-flowered scorpioid recurring forks 1-2 inches long; lower flowers shortly pedicellate. Calyx $\frac{1}{2}$ inch long, deltoid teeth twice as long as the tube. Petals bright yellow, linear, twice as long as the calyx. Stamens a little shorter than the petals. Carpels as long as the filaments, narrowed gradually into a style half as long as the ovary. Parts of the flower in sixes to eights, or even tens.

A strictly Mediterranean species, extending from Spain and the South of France eastward to Syria. It flowers before any of the others, and is marked at a glance by its very distinctive leaves and very lax few-flowered cymes, which consist of only from six to fifteen flowers, whilst all the others have thirty, forty, or more. In Spain it ascends the mountains to a height of 8000 feet, so that it is quite hardy in England. The specimen that stands as the type of rupestris in the Linnean Herbarium is one of this species sent from Spain by Loefling. *F. G. Baker.*

Natural History.

I AM tempted to send you an account which has frequently struck me as remarkable, and somewhat amusing as well. The gamekeeper (Mr. Drewett, Norton Manor) set a hen with the usual number of eggs, and by accident a duck's egg happened to be amongst the batch, and in due course the chickens and the young duck grew up together in harmony to the present time, when they are nearly their full size. There are plenty of ducks close by, and, still more tempting one would think, there is a broad trout stream, where the other web-footed family are enjoying themselves most thoroughly, but this duck does not leave his chicken friends to take to the water, but follows his companions wherever they go, and as they can travel faster than he, and he is left behind, it is amusing to see him stop, and with very loud "quacks" call their attention to the subject. Some short time since, while conversing with the above gentleman, a hawk made a dash amongst the poultry. There was amongst the ducks a scramble for the water, but the peculiar one I write about dashed under the bushes with the hens, &c. One would have thought that "instinct" would have prompted the subject of this paper to take to the water with his own kind. *William Payne, Taunton.*

SHOOTING WILD BIRDS.—I hardly know how to defend myself from "A. D.'s" attack upon me for shooting a landrail. These birds are not very rare, it is true. I have not failed to flush and bag several in the early part of the partridge season during many years past. I have shot them, sir, for thirty years, and intend to continue the diversion whenever a favourable opportunity occurs. "How cruel!" says "A. D." Yes; but the game birds owe us something; in fact, they owe us their lives, which they enjoy till the last moment, and which sportsmen and game preservers render possible, and—till that last moment—safe. There would be no game but for

sportsmen, and there would be so much the less of that innocent and happy life to which "A. D." alludes. And in that case the grub and insect pest in fields and gardens would become still more serious. Then where would "A. D." slip in his objections to this kind of destruction? He speaks of harmless birds, and would draw the line with them perhaps. Does he eat mutton? I hope that he rejoices in a double row of unimpaired grinders. And if so, I would ask him to consider how he came by a set of teeth common to the carnivora? *Subscriber.*

—After abusing sportsmen and libelling school-boys "A. D.," at p. 430 says:—"No doubt the handling of a gun has a demoralising influence on the mind, as there comes with it the anxious desire to use it upon whatever object may present itself"! Surely, sir, this is one of the most astounding propositions that ever appeared in print, and is only equalled by the maudlin sentimentality of the rest of the article. There can be no more harm or cruelty in shooting a landrail than in killing a rabbit or any other animal in a legitimate manner. What next, and next? *P. O. M.*

HABITS OF THE CUCKOO.—The two following lines embody the Yorkshire countryman's notions of the egg-sucking habit of the cuckoo, alluded to in last week's *Gardeners' Chronicle*, p. 430. I recollect hearing them some sixty years ago—

"She sicks little birds' eggs to make her voice clear,
And sings cuckoo, cuckoo, three months in the year."
I. O. Westwood.

Apiary.

INTRODUCING ITALIAN QUEENS.—Any one wishing to introduce Ligurian bees into their apiary should do so as early in October as possible. We recommend this month, because a fertile and young imported queen may now be purchased for a few shillings, whereas if the early part of the honey season be selected they are expensive. To many persons the safe introduction of queens has seemed a very difficult operation, but if the following plan be adopted they can be introduced with certainty, though after every care has been exercised sometimes failure occurs. First select a fine day, and having discovered the black queen, let her be carefully placed in a small perforated box containing a small piece of honeycomb suspended in the centre, together with a score or two of workers. We recommend this because if failure occurs, and the Italian queen should be unfortunately killed, you will have the original queen still, which may prevent the destruction of the entire colony. A small cage may be made by the most inexperienced of wire-cloth, having eight or ten meshes to the square inch, a piece 3 by 4 inches rolled or folded so as to bring the edges together, and having each end stopped with bits of cork. This answers quite as well as the most fashionable queen cage to introduce the new queen. Immediately after removing the common queen—many practical beekeepers say "stop until about twenty-four hours afterwards, in the meantime the colony will have found out or discovered their loss, then they will take to the Italian queen with demonstrations of joy;" take our advice, do it at once; it will succeed far better—place the wire cage containing the Italian queen with a few of the workers sent with her between the tops of the central combs, and against sealed honey if possible. About sundown the following day, after giving the bees a little smoke to quiet them, open the hive, and drizzle honey in a fine stream between the combs and on the tops of the frames; then allow the Italian queen to crawl down between the combs, completely daubing the lower part of her body with honey as she is leaving the cage. Close the hive at once, and contract the entrance the whole of the day following, giving sufficient room only for the exit of one bee at a time. On the second day examine the combs to assure yourself of the safety of the new mother. This latter is almost superfluous advice, though it is perhaps advisable. In all cases, especially in the active season, if the hive has been queenless for longer than a day, you must destroy all the queen cells which may be in process of formation before releasing the new queen, as the result may be serious. It will be observed we are speaking only of introducing a new queen to the bar frame hive. In the case of an ordinary skep first drive the bees into an empty hive, then knocking the bees out on a white cloth before the hive on a table,

search for the old queen. The new one may then be introduced as above recommended, though it is better to cut a small opening through the straw in the centre of the hive or just in the crown. *R.*

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—Where plants are grown successfully there is no course but one with respect to insects—that is, waging an incessant war against them. To succeed with even the numbers that at the present day are found in a medium-sized collection, at least one-third the labour involved in their entire cultivation may be set down to the necessary continuous struggle that has to be kept up with the insects that prey upon them, and not only will those who are the most assiduous in keeping these animal parasites under, attain the greatest success with the plants they grow, but it will also be found that the old maxim of the "stitch in time" being a great saying is in this matter more correct than with many things, independently of the more healthy appearance that plants always have that are kept clear from the various pests that attack them. Even with greenhouse subjects, the foliage of which is usually of a hardier nature, and better calculated, without injury, to withstand the different operations necessary for the destruction of insects according to their kinds than the more tender stove species, at no time will they suffer so little from the effects of brushing, sponging, or washing with insecticide as at the present. With Camellias particularly, it rarely happens that a collection, however limited, is perfectly free from scale, especially the white species, which from its tenacity of life, is enabled to withstand a stronger application of the various liquids employed for the destruction of animal life than the plants in most cases will bear; even in the case of such as have at different times through the season been gone over, it is well now to give them a general overhauling, as if deferred later, when the buds of the early flowering kinds begin to swell, the brushing and sponging necessary often causes a considerable number to drop further on. With plants that are badly affected, and where the scale is allowed to get to a great head, so as to exist in large numbers among the flower-buds, it induces a stunted, unhealthy condition, to which a general loss of buds is often attributable. The whole of the wood and leaves, both on their upper and under surface, with every crevice in the bark, should be carefully brushed over, and afterwards sponged so as to leave the foliage bright and glossy. Inexperienced hands are sometimes set to this sort of work, and if an overhand brush is used without care the leaves are often seriously disfigured. In the case of large specimens planted out, it is more necessary to be careful that not a single branch of the plants affected escapes the operator. In respect to brown-scale this is not nearly so injurious in its effects upon the plants as the white species, confining itself much more to the leaves than the flower and wood buds, but it has the effect of making the foliage much more dirty by the excremental deposit which it leaves upon it, the glutinous nature of which attracts every particle of dust that comes near it, giving an unsightly appearance as well as injuring the leaves by closing up their pores. These cleaning operations should not at the present season alone be confined to Camellias, but extended to other plants that are affected, especially such things as Acacias, Cytisus, Oranges, Correas, Myrtles, Neriums, Statice, and similar things, that are generally more or less affected with these insects. Amongst fine-leaved plants that suffer from them are Yuccas, Cordylines, Dracenas, and others of like habit. When these are infested with white-scale it is very troublesome, as it gets down into the axils of the leaves so low that it is difficult to remove it without doing injury. In the case of such I have found "Abyssinian Mixture," at 8 oz. to the gallon, applied with a sponge, so as to moisten the affected parts, the most effectual, giving two or three successional dressings as required until the insects were destroyed. Greenhouse and conservatory climbers should now also have an extra cleaning, reducing the strong growth within reasonable limits to facilitate the work. Any that are very badly affected may be cut back, taken off the wires, and their heads dipped in a strong solution of the mixture, allowing them to remain immersed in it for an hour or so, which will be found much more effectual than simply dipping or syringing, as the solution reaches every part.

In conservatories generally at this time there is a paucity of flowers, but where some Fuchsias have, as advised, been especially prepared for late blooming along with such things as Statice, Croweas, the beautiful blue *Witsenia corymbosa*, Veronicas, either grown in pots or planted out and lifted; *Belladonna Lilies*, and the many coloured *Celosias*, the feathery form and numerous bright shades of which, combined with their easy growth and long-enduring capabilities renders this last one of the best and most useful plants

that can be grown for autumn decoration—by the help of these, tastefully arranged amongst fine-leaved plants, the latter judiciously selected and well-grown, a very pleasing effect may be produced. In no situation are Tree Ferns seen to greater advantage than occupying a position in the centre of a cool conservatory when the plants employed are proportionate in size to that of the house, but in all cases with stems sufficiently high to admit of the fronds considerably overtopping the other occupants. From the moisture-loving nature of Tree Ferns generally many are led to suppose that they cannot be successfully grown in a house where the atmosphere is not considerably humid, yet such is by no means the case. *Dicksonia antarctica* and the nearly allied species, *D. squarrosa*, can be had in beautiful condition in an ordinary greenhouse, requiring much less shade under such treatment than when grown with more heat and moisture. All that is necessary is a plentiful supply of water to the roots. The fronds, as a matter of course, do not grow so large; but this in many cases is a decided advantage, and they are much more persistent than when grown in a way that imparts greater size, with less enduring qualities. In a comparatively dry atmosphere of this kind they sometimes assume a somewhat yellowish tint. This can be corrected by the use of manure-water, to which few plants are more partial. By its free application Tree Ferns may be kept for a long time in a luxuriant condition in comparatively small pots or tubs. The strong-growing—often to an extent that renders it unmanageable—*Cyathea medullaris*, kept in such a house assumes quite a different character, the fronds not attaining a size more than one-third of that which they grow to in a moist fernery. *T. Baines.*

FRUIT HOUSES.

PINES.—The temperatures, as given in the preceding Calendar for Pines, should remain in force during the present month unless very unfavourable conditions prevail outdoors, and then, rather than have recourse to very hard firing for the purpose of sustaining the heat at the maximum point, it will prove much more beneficial to the well-being of the plants to allow the heat about them to recede a few degrees. The advantage accruing from covering up Pine structures at night, during the prevalence of inclement weather, cannot be over-estimated, both in an economical and beneficial point of view; therefore, it should be adopted wherever practicable. To counterbalance the diminishing force of sunshine, &c., at this season the glass should be kept free from any obstacles which will hinder the free access of these elements to the plants; therefore, let the residue of any composition which may have been used for shading purposes be thoroughly cleared off now, and let shading likewise be abolished altogether for the season. Any alteration which may be required in the way of renewing the beds or rearranging plants in places such as those which necessitates exposing the plants should, as far as practicable, be done before the advent of severe weather. In the case of fermenting beds which are required to hold the heat for a considerable period onwards, attention should be given. If the old materials have become exhausted new beds should be made, otherwise an addition of one-half fresh material will suffice. If tan is procurable at the rate of about 4s. or 5s. a load, it is doubtless in the end less costly than any other substance which is employed for this purpose. Pursue the course of treatment already detailed for each class of plants in this department. Be circumspect in the application of water at the roots, particularly with respect to plants which were plunged in beds having only a moderate degree of heat in them, and in the case of others only give it when actually required, and then abundantly. Keep the plants free from suckers by screwing them out until the fruit is starting, when one on each plant should be allowed to grow. Suckers which may have been recently potted should not be crowded thickly together, and should be kept well up to the glass in order to keep them in a sturdy condition; at this naturally damp period in the year it is advisable to remove from the fruiting house any ripe fruits which are not to be cut at once. These can be placed in a late vinery, or similar place, where they will keep a considerable time. *Geo. T. Miles, Wycombe Abbey.*

ORCHARD HOUSE.—With the exception of a few late Plums, Peaches, and Figs, the pot-fruit season may now be considered over, and the zealous cultivator will be devoting his attention to the thorough ripening of the wood, without which a good set of fruit cannot be expected next year; the removal of all surplus and crowded growths, so as to admit of full exposure of the remaining spurs and shoots intended for producing the next crop. Let all potting or shifting be completed as the foliage shows signs of ripening, using strong calcareous loam, with a liberal admixture of crushed bones and burnt earth, or lime rubble. Use clean pots carefully crocked, ram the compost very firm, and protect from heavy rains if it is thought advisable to keep the trees out-of-doors for a time, at the same time care must be taken that stone-fruit trees do

not get too dry through the winter, as many fine and promising Peaches and Nectarines cast their buds in the spring through this cause alone. Half-ripened wood, and imperfectly ventilated houses will also cause dropping. To prevent the annoyance of seeing buds fall when they should be expanding into life and beauty, keep the old foliage clean and healthy, get the wood thoroughly ripe, give sufficient water to keep the soil in a healthy growing state, and avoid premature excitement in mild weather by reducing the temperature of the house to that of the open air. If trees for potting up have not been selected no time should be lost in getting them marked, as the demand this autumn will be very great, and it is hardly necessary for me to say the most promising trees are sold first. *W. Coleman, Eastnor Castle.*

KITCHEN GARDEN.

The beds of Cabbage intended to stand through the winter should now be thoroughly hoed over deeply, and if found necessary the earth may be drawn up to the plants, but they will scarcely be sufficiently advanced, and if the earth is moved deeply that operation may be deferred for some time. The beds of winter Spinach will also be much benefited by having the soil deeply stirred amongst the plants. At this season the seeds of weeds are apt to germinate very freely amongst these and all other recent plantations of vegetables, particularly Lettuces and Endive, and we cannot practise a better method than frequent stirring of the surface as often as they show themselves, for if they are left to grow it is double the labour to clear them off, and the beds never look so neat as when they are taken in time. This frequent stirring is also of great benefit in disturbing the slugs, which in moist weather are often very destructive at this season; constantly moving the ground puzzles them, as they cannot then get about freely and the plants soon grow away from them; if however, they are very numerous, sprinkling with fine quicklime will soon reduce their numbers. The splendid weather we have lately been favoured with has afforded excellent opportunities for tying up and otherwise preparing Endive and Lettuces for planting in pits or other suitable places where they can be protected for use during severe weather; the time of tying up is the most important, as the foliage should be thoroughly dry, and therefore the middle of the day should always be selected for the purpose. In taking up for storing, which should be before the advent of frosts, take care to retain a fair-sized ball of earth to each plant, and plunge them in the pit as close as they can be planted without touching; the after care will consist of plenty of ventilation in favourable and protection in severe weather. The Cauliflowers sown at the end of August will now have attained sufficient strength for planting under handlights as well as for potting up, as before recommended. In preparing the ground for handlights, the soil should first be deeply trenched up and well pulverised; the necessary manure, which should be applied with a liberal hand, should then be spread over the surface and pricked in. By the way, referring to manure to be pricked in, it should always be understood that it should be in a thoroughly decomposed state, for if only half decayed stuff can be had it had better be incorporated with the soil during the process of trenching. After turning in manure, level the surface, and dress the whole over with lime and soot mixed together in a dry state. Slugs are very partial to young Cauliflower plants, and this preliminary dressing will so check them that the plants will have time to establish themselves and make a start, when, if found necessary the dressing may be repeated. It is usual to have five plants to each handlight, but it is a good plan to put in double the number as they are easily removed if not required and used for filling up vacancies. Attention must now be given to the lifting and storing of all fusiform roots. Red Beet especially is impatient of frost, and must be lifted at once, great care being taken to keep the roots as intact as possible, as bruises are apt to let out the colouring matter in the process of cooking, for this reason the leaves must not be cut off within 1 inch of the solid root. In storing avoid placing them together in any bulk, as the effects of heating are injurious; our plan is to place the roots in an upright position in a deep trench in one of the out-buildings, placing them close together and filling up all the interstices with sand as the operation proceeds, and spreading a layer of 3 inches of sand over the top. Carrots, which should be lifted at once, should be stored in the same manner if room will serve, but in any case care must be taken to store them in such a position as precludes the possibility of heating, which is the great agent in producing rotteness and decay. Salsify and Scorzonera had better be lifted at once and stored, but Parsnips are better left in the ground and only lifted as required. Where Parsley is in much request during the winter it is a good plan to take up any surplus plants from the beds and pot them; they may be placed in a cold pit, or orchard-house, or a dormant vinery, so that a few can be taken at a time and placed in heat. *John Cox, Redleaf.*

THE
Gardeners' Chronicle.

SATURDAY, OCTOBER 13, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	Oct. 15	{ Sale of Dutch Bulbs at Stevens' Rooms (and 17th).
THURSDAY,	Oct. 18	{ Sale of Greenhouse Plants, at Clapham Common, by Stevens.
FRIDAY,	Oct. 19	{ Sale of Orchids, at Stevens' Rooms.
SATURDAY,	Oct. 20	{ Sale of Dutch Bulbs, at Stevens' Rooms.

A SHORT time since we announced the fact that an addition had been made to our dessert fruits in the shape of the so-called Mexican Apple, CASIMIROA EDULIS. We now lay before our readers a figure of the fruit (fig. 91), and avail ourselves of the opportunity again to call attention to this very interesting plant. It owes its presence in our gardens to the late Dr. SEEMANN, who met with it in Nicaragua, and sent it to Mr. BULL, by whom it was distributed some nine or ten years ago. Since that time we have heard little or nothing about it, till a few weeks ago we had the pleasure of seeing and tasting fruits ripened in the gardens of Mr. MITCHELL HENRY, M.P., at Kylemore Castle, Galway, under the care of Mr. GARNIER. Mr. GARNIER, in reply to our enquiries, has kindly furnished us with the following particulars:—"The tree is now about 10 feet high, with a clear straight stem and a beautifully formed head, about 5 feet through. It seems to require some years before it produces fruit, as it showed no signs of fruiting until two years ago, when it showed some small fruits about the size of pullet's eggs, which, however, did not come to maturity. This year, however, I was agreeably surprised to see the fruit swell to the size of a good specimen of a St. Michael's Orange. As you will see, the tree is very prolific. The samples sent are not so fine as those which were sent to my employer's table, where the guests one and all pronounced them excellent. I myself consider it the best of all the tropical fruits with which I am acquainted. It begins to grow now (end of September) just as the other fruit is gathered, and swells very fast, completing its full growth very rapidly. The fruit is borne on the two-year-old wood, not in the axils of the leaves; it is of a greenish yellow colour when ripe, and had a delicious melting flavour like that of a Peach. I grow it in rich friable loam, mixed with a little peat, and if the drainage is perfect do not disturb its roots. The tropical-house here is a large and lofty span-roofed structure, and is never heated much more than to an intermediate temperature."

The specimens we tasted had evidently been gathered before they were fully ripe, but, making allowance for this circumstance, we are quite disposed to endorse the favourable verdict above given as to the merits of this fruit.

Casimiroa, though it has received the name of "Apple," is more strictly an Orange. The foliage and the outer parts of the flower are studded with transparent oil cysts, as in the Orange, but the leaves are digitate, like those of the Horse Chestnut, and the flowers are less conspicuous than those of true Oranges, and the number of stamens less; still, there is no doubt as to the close relationship of the plant to the Oranges and allied plants. The tree is a native of Mexico, where it is found in a wild and cultivated state; it has also been widely distributed through various parts of America. The best account of the tree is that contained in SEEMANN'S *Botany of the Herald*, from which we borrow what follows:—"This tree has a remarkable tendency to accommodate itself to different climates; it grows from the lowest coast region to an elevation of 7000 feet, producing everywhere an abundant harvest. The

fruit is said to produce a somniferous effect." Dr. SEEMANN goes on to quote the Latin account given by the Spanish writer, HERNANDEZ, in 1790, from which we condense the following particulars. The tree is large and of loose habit—"incondita;" the leaves are like those of the Citron, thin and ternate. The fruit is of the form and size of a Quince, and is called by the Spaniards *Zapote Blanco*. It is edible, of a pleasant flavour, but not very wholesome, the kernel of the seeds (*ossis nucleo*) being deadly and injurious—"lethalis ac deleterio." After citing various medical and surgical purposes to which the leaves and powdered seeds may be applied, he goes on to say that the fruits when eaten promote sleep, a circumstance which has given rise to the Mexican native name, which we will not inflict on our readers—"Poma ingesta somnum conciliant a quo invenerunt nomen." HERNANDEZ also notices that the tree grows in warm and in cold districts.

It seems clear, then, that in its native country it is looked on with some degree of suspicion, though not to such an extent as to prevent its being eaten as a fruit. While the fruit is said to promote sleep, a much worse character is given to the seeds. These statements point to the necessity of caution—a caution the more needed from its delicious flavour. Who knows but that some modern Circe might tempt to their destruction the unwary partakers of a dessert of which Casimiroa fruits formed a part! Seriously, while we would urge the necessity of caution in partaking too largely of this fruit, and especially of its seeds—a caution not likely to be wanted for some time to come we expect, and in the case of the seeds not at all, as their bitter flavour is not very palatable—we would at the same time express an opinion that, partaken in moderation, the fruit is no more likely to be injurious than so many Cherries or Peaches, the seeds of which might also be truly described as *lethalia et deleteria*; and as for the alleged soporific qualities we do not imagine them to be much more potent than those of the Lettuce. Still, we are reasoning from analogy only, and would by all means advocate caution. Only let this caution be exercised with judgment, else a really valuable fruit may be unjustly discredited.

Judging from its botanical affinities the tree might perhaps be grafted with success on the Orange. Judging also from Mr. GARNIER'S statement, it might be worth trying in an orchard-house, and might even succeed out-of-doors in the climate of the Scilly Isles or southwest Ireland, if not too moist. Undoubtedly in many parts of India, the Cape, and the Australian colonies it would prove a valuable introduction. Let our colonial friends look to it. In the meantime will some correspondent acquainted with the natural products of Mexico tell us how many of the fruits on the average a healthy adult may partake of with impunity? We know that the number of mutton chops that can be taken without harm is limited, so that we are quite prepared to hear that there are bounds and limits beyond which Casimiroa cannot safely be eaten. Even the Fungus eaters at Hereford, whose doings we chronicle this week, would admit so much against even *Lactarius deliciosus*.

YEAR after year we experience unpleasant reminders of "how they do things in France." Strange to say, we and ROSE BUYERS in particular do not profit by the experience. Year after year the tempting bait is offered—Madame la Comtesse de Méprise, La Marquise de Tromperie, Monsieur Joli-Vert, and a host of other Rose celebrities, are paraded as anxious for the honour of our acquaintance. To induce us to accede to the proposal their *signalement* is printed in brief but flattering terms—*st. gr., bien faite, rose tendre, parfum exquis, très vigoureux,*

remonte franchement, &c. A slight consideration is all that is demanded—a matter of a few francs, a bagatelle for so great honour. Twenty-five francs for a real Duchesse—who would hesitate? Besides, there is the usual trade reduction if we be traders; a few months' credit will be given if required, but, singularly enough, the period of credit is not long enough to enable us to see our new acquaintances in the flower before we have to pay!

Rose buyers know too well that all this is true, and yet they buy, and will continue to do so so long as novelties are in demand. But it may fairly be asked of French Rose growers, who, as a body of men, are worthy of all respect, why they do not combine to stop the wholesale influx of untried or inferior varieties. Is there no body of capable and conscientious growers in France to pass judicial opinions on new Roses, and to award certificates accordingly? Our own Floral Committee, though, like human-aggregates in general, it fails sometimes, yet does its work so honestly and well on the whole that its verdict is respected and acted on by the trade.

Could not a deputation from the Rose growers attend a meeting of our committee, or of that of one of the great Rose shows, and see how new seedlings and varieties are adjudicated upon, and then go back to their compatriots, form a like tribunal, and specially beseech their compatriots to refrain from flooding us with indifferent Roses?

We have before us a list of new French Roses purchased during the last five years, with their qualities and the names of their raisers. The list comprises 165 varieties in all. Of these, in our judgment, seventy-five are fairly good, with a few, such as Etienne Levet, François Michelson, Captain Christy, Hippolyte Jamin, Mons. E. Y. Teas, Abel Carrière, Duchesse de Vallambrosa, &c., really first-class Roses. The remaining ninety are indifferent or bad, some even have not afforded us the opportunity of estimating their merits, for they have never bloomed. We are sure that the verdict of Rose growers generally will not be greatly different from this. Last year's importation, we have reason to believe, is one of the worst, if not the worst, of the series. A timely caution to buyers, now that the Rose lists are coming in, may serve to prevent much disappointment to traders and heartburning among amateurs.

— WE hope to be able to publish in our next issue some account of the remarkable discovery of a FOSSIL RESTING-SPORE, with its mycelium, closely similar to the recent Peronospora of the Potato disease, by Mr. W. G. SMITH. In the same number we hope to present our readers with a COLOURED PLATE illustrative of some EDIBLE and NEXIOUS FUNGI, and showing the distinctions between the true Mushrooms and some other fungi that have a general resemblance to them.

— At the meeting of the Woolhope Club, held at Hereford on Oct. 4, M. MAXIME CORNU, of Paris, described A NEW DISEASE OF THE VINE, which had been brought under his notice in plants from the neighbourhood of Narbonne. It is there called "Anthracose" because it appears like dark burnt spots on the leaves and branches of the Vine, and even on the Grapes themselves. In the first or conidial stage the spots are white, and in the second stage they present the blackened and charcoal-like appearance that has given the popular name to the disease. It belongs to a fungus named by BERKELEY and CURTIS *Phoma uvicola*. Its third condition is yet to be observed. The disease has been introduced to France with young plants from America, and has now been observed in several places. The Vines are also attacked by another fungus named *Cladosporium viticolum* of CESATI, which may be recognised by its dark brown velvety spots which have been known for some years, and now it has been pointed out by Dr. FARLOW at Boston that the French Vines in America are attacked by an ally of the Potato fungus in *Peronospora viticolum*, which attacks the young shoots and branches in the most destructive manner. M. CORNU

FIG. 91.—CASIMIROA EDULIS, NAT. SIZE; ONE FRUIT CUT TRANSVERSELY; CRYSTALS AND CELLS OF EPIDERMIS OF FRUIT ENLARGED 160 DIAM.

dwelt on the great importance of the most careful attention to the study of these diseases, and called for the assistance of English mycologists in their observation. The remarks were illustrated by most carefully executed drawings of the fungi named above and illustrations of their effects on the leaves, stems, and fruit of the Vine.

— It appears from a communication made to the Brandenburg Society of Botanists that *COLLOMIA GRANDIFLORA*, a North American plant, is thoroughly naturalised and exceedingly abundant in some parts of Germany. In very stony places it grows only 2 to 6 inches high, and these plants bear exclusively cleistogamic flowers—that is, small closed flowers without petals, in which self-fertilisation must take place. Where they are stronger they bear both small closed flowers and ordinary open ones, or only the latter. It threatens to become a troublesome weed in cornfields, as it seeds very freely, and spreads rapidly, and the seeds are projected to a considerable distance when the capsule opens under the influence of the sun.

— The *GLOIRE DE DIJON ROSE*, we are told by the *Journal des Roses*, was raised by MM. JACOTOT, nurserymen, of Dijon, in 1849, as a seedling. Unfortunately, the parentage is not given. It was first publicly exhibited in 1852, and "sent out" in 1853. It remains decidedly one of the best all-round Roses, and if we had to grow but two, they would be *Gloire de Dijon* and Charles Lefebvre.

— It must be a time for anxiety on the part of some *CHRYSANTHEMUM* cultivators as to whether the flowers will be expanded in time for the usual exhibitions of this popular autumn flower. The plants are generally very late this season, and some growers are housing them earlier than usual, to hasten the flowering period. The plants should now be fast showing their bloom-buds. Cultivators who like to have nicely rounded heads of fine blooms to their plants make a practice of removing all side blooms, leaving only the buds at the extremity of each shoot; and by doing this a plant when in flower will present one head of uniform and well-developed blooms. Such plants are better for, and more effective as, conservatory decorative plants. A few thoroughly good flowers are surely to be preferred to a large number small in size and confused in appearance. A little manure-water will be found of great service just now. Those who grow solely for specimen blooms to cut for the exhibition table must keep a sharp look-out for earwigs. They insinuate themselves into the space immediately about the bud, and so completely hide themselves from view that they are only detected when closely looked for. If undiscovered they work irretrievable damage. There is something in selecting the right buds. A successful cultivator once remarked: "In choosing the buds select only those which are perfectly round and bright in colour. Remove dull-coloured, brownish looking buds in every case, for if they swell or expand at all they will only produce malformed blooms." A little warmth—as, for instance, that of a greenhouse with artificial heat—greatly assists the development of the flowers. Manure-water must be used freely as the buds expand, and it is best applied when the plants are moderately dry.

— Messrs. EDWARD WEBB & SONS' ANNUAL ROOT SHOW, at Wordsley, is announced to be held on Tuesday, November 20. Entries for root crops close on Tuesday, October 23, whilst those for specimen roots and cereals close on Tuesday, November 13, and the latest day for receiving roots and cereals intended for competition is Thursday, November 15.

— Complaints are sometimes made that the *CINERARIA* is a difficult plant to winter, and when such a lament is heard the results so much deplored in all probability are traceable to coddling and imperfect management. The *Cineraria* is a much hardier plant than is generally supposed, and can be wintered in a cold pit or frame if there be a good dry bottom. If the pit is deep the plants should be stood on inverted flower-pots, it brings them nearer the glass, and raises them to a dry position above the floor of the frame. If frosty nights threaten an ordinary garden mat thrown over the frame will keep all snug. The lights should be lifted off, and all possible air given in suitable

weather to keep the plants compact and lusty, and inure them to severity of weather. The earliest among the plants will, in all probability, be throwing up their flower-stems, and if they be put in a greenhouse some early bloom will appear. Water should be given somewhat sparingly when the weather is dull and cold. The great enemies of the *Cineraria* at this time of year are the mildew and green-fly. For the last a lawful excuse can scarcely be found; tobacco in some form or the other will speedily settle them, either by fumigating with the smoke, or syringing with some prepared solution. The mildew will appear in spite of all efforts, and is not so easily disposed of. The best remedy is to dust the affected parts with flowers of sulphur as soon as discovered, and if the remedy gives the plants an unsightly appearance for a time it is at least effectual, and the only sure remedy at present known.

— One of the most attractive of variegated coniferous plants is *Cupressus Lawsoniana lutea*. It stands well and is decidedly one of the best golden Conifers in cultivation, as the variety known as *aurca* is not nearly so well variegated nor so compact in growth. What is known as *FRASER'S* variety of *C. Lawsoniana erecta* is also a very desirable plant, taking on a handsome upright growth. A variety of the Spruce Fir known as *Abies Finedonensis* is now very ornamental in Messrs. JOHN PERKINS & SON'S Nurseries at Northampton. It is a good and distinct sport, obtained in the neighbourhood of Finedon, and has been in the locality for many years.

— Mr. D. MACRAE, late foreman at the Duke of GRAFTON'S, has been appointed gardener to Lieut.-Col. H. BAGOT-LANE, Lichfield.

— We have received from Mr. PARKER, of Tooting, some well-grown examples of the very distinct and desirable *GLADIOLUS SAUNDERSII*. This is a recently introduced species, and one which, along with *G. cruentus*, may be expected to have an influence on the hybrids of the future, in which at the present time *G. gandavensis* (bred from *G. psittacicus*) is predominant. The plant grows from 2½ to 3 feet high, with a long terminal spike of large flowers of a brilliant scarlet, the two lateral sepaline divisions of the perianth being faintly speckled with white. The leaves are fully 1 inch broad, and of the usual sword-shaped character. It is remarkably showy, and should find a place on its own merits in every collection of hardy bulbs. The plants before us, now blooming from lateral branches, had their principal spikes in blossom fully two months since, and were then, as now, remarkable for the brilliancy of their colour.

— We hear that Mr. CARMICHAEL, late of the gardens, Sandringham, and more recently of Crowe Hall, Bath, has just been appointed gardener and steward to A. PORTEUS OAKES, Esq., of Norton Court, Bury St. Edmunds, and will enter on his new duties on November 1. Mr. OAKES is thoroughly remodelling his pleasure-grounds at Norton, which are well stocked with choice Conifers, and a large new kitchen garden is about to be formed and furnished.

— Sir JOSEPH HOOKER, we learn, left Boston on the 6th, after spending some days in that city with Professor ASA GRAY, for the purpose of arranging the large collections of dried plants made by them in their recent trip in the Western States of America. We may look forward to some very interesting details concerning the botany and geology of the districts travelled over.

— Mr. HALL, who for the last seventeen years has held the post of head gardener to the Right Hon. the Earl of SCARBOROUGH, at Sandbeck Park, near Rotherham, has been appointed by his lordship to the management (under the chief agent) of his Lumley Castle estate.

— According to the *Irish Farmers' Gazette*, the GREAT VINE AT THE VICEREGAL LODGE, Phoenix Park, is at least one of the finest examples of a single Vine grown on what is called the extension system, to be found in these islands. It is quite possible and very probable, our contemporary admits, that there

are other monster Vines monopolising entire houses, and covering a larger space; but he doubts if the Finchley or any other celebrity in its way presents such a picture of successful Grape culture as does at this present moment the large Vine at the Viceroyal Lodge. The crop is the heaviest it has yet matured, the size and weight of the bunches being beyond the average; not a few would turn the scale between 3 lb. and 4 lb. weight, and the general run of bunches is fully 2 lb. each. The number of bunches is somewhere about 500, the heaviest, of course, being at the extreme end of the house opposite to that at which the Vine is introduced, and from which rods are conducted horizontally the entire length of over 70 feet. Nothing can be more robust, clean, and healthy, than the foliage. Altogether it is a triumph of cultural skill and good management.

— We hear that Mr. FOWLER, of Castle Kennedy, has lately been working at the improvement of the race of DWARF BEDDING AGERATUMS, and has obtained some seedlings of great promise. He has been growing them by the thousand, and our informant states that he was specially struck with one named Cupid, having blue flowers, a dwarf habit, and very free-flowering qualities—in fact quite a rival of *Lobelia speciosa*. Another dwarf and free-flowering variety, named The Queen, is the nearest approach to a white that our correspondent has seen. We should be glad to hear more of these novelties.

— Mr. BARR has sent us a twofold novelty in the shape of the pretty sweet-scented IRIS ALATA flowering in a HYACINTH GLASS. The interest is by no means in the novelty only, and we have no doubt that when others see the plant so grown, they will be desirous of adopting it as a welcome change from the Hyacinths.

— We hear that Signor BECCARI is likely to succeed Professor PARLATORE as Director of the Herbarium and Botanic Garden at FLORENCE, if arrangements can be made for some other Professor to undertake the duties of lecturing. It is not every one who combines the administrative qualities requisite in the director of a large scientific establishment with those of a competent teacher. The irksomeness of teaching, and the interruption to original work, are also severely felt by many. It is clearly desirable in such cases that a division of labour should be carried out, though we are strongly of opinion that great advantage both to the director and to the public ensues from the occasional delivery of a lecture on some special point of study which has occupied the director's attention.

MR. PARKER'S NURSERY, TOOTING.

MR. PARKER'S speciality is undoubtedly alpine and herbaceous plants, and call at his nursery when you will there is always something to be seen and admired—some rare or beautiful gem to feast your eyes upon; and if you don't find a fit subject for admiration amongst this class, you will amongst some others, for Mr. Parker has a *penchant* for the best of everything, makes his selections with rare judgment, and cultivates the objects of his choice in a style of proficiency that comes only of wide practical experience and years of lynx-eyed observation of Nature, as Nature is found amongst cultivated plants. His nursery is a model of order, neatness, and good cultivation, and every plant you may see there belongs to the front rank in its class or genus, so persistently is the weeding-out process carried out. No wonder, then, that the Exotic Nursery has gained such a high reputation as it now enjoys. Our last visit was made a couple of months ago, when we found the nursery in quite a blaze of bloom, Phloxes and Pyrethrums being then at their best, and flowering plants of some kind or other, here, there, and everywhere.

The remarkably showy Phloxes of the *decussata* and *omniflora* types were in fine flower, and presented a very brilliant appearance. Mr. Parker has weeded out all but the most approved flowers, and grows these strong and well, to fully bring out their true characters, with the result in the end of producing a rich floral *tableau*—a perfect *embarras de richesse* of high colours and exquisite forms. Where all are so good it is somewhat embarrassing to make a selection,

nevertheless we shall attempt it, and note the very cream of the varieties then in bloom. The pride of place we give to the charming *coccinea*, so rich is its colour, so neat and floriferous its habit. Next on our list comes Madame Thibaut, amaranth-red, with crimson centre; Madame Domage, white, with carmine centre; Danaë, creamy white, with purplish carmine centre; Madame Cannart d'Hamale, salmon-rose, with crimson centre; Madame Autin, purplish crimson, with purple centre; Lothair, bright scarlet, with crimson centre—a great beauty; Madame Andry, purplish crimson, with crimson centre; La Candeur, white, with broad rosy purple centre; J. K. Lord, salmon red, with fine carmine centre; Gloire de Poiteau, clear rosy lilac, with a white centre, a fine old variety, with a rare constitution; Sultana, dark salmon-pink, with crimson centre; Mons. Donnaud, a salmon-red, with crimson centre; Richard Wallace, white, with a bright carmine centre; The Queen, a remarkably fine pure white; Baron Duruffe, purplish crimson, with crimson centre; Lucien Tisserand, mauve, with crimson centre; Madame Andry, rich crimson purple, with crimson centre; Princess of Wales, white, suffused with rose; Sparte, rosy purple, with crimson centre; Professor Koch, rosy salmon, with rich crimson centre; Menotti, rosy lilac, with white centre; and Madame Moisset, bright rose, with a rosy crimson centre. Selecting from these a dozen of the best for bedding purposes we have *coccinea*, Gloire de Poiteau, Lothair, Lucien Tisserand, Madame Andry, Madame Moisset, Menotti, Princess of Wales, Professor Koch, Richard Wallace, Sparte, and the Queen, all of which have a fine branching habit, with flowers of perfect form and purity of colour. These varieties all belong to the *decussata* type. In the *omniflora* section the most noteworthy variety that we saw was a charming bedding variety named Countess of Sefton, which only grows to the height of 8 inches, has white flowers with a purple centre, very pretty, and a free bloomer.

The first plant that specially claimed our attention in the herbaceous border was *Hydrangea paniculata grandiflora* (figured at p. 653, vol. iv.), with its fine large panicles of white flowers just opening. Here is a row of good plants, that have since been masses of bloom for about two months. It is a thoroughly good thing, and deserves a wide range of cultivation. For producing striking effects in the mixed border *Symphytum officinale sulphureum variegatum* struck us as being a particularly useful subject, on account of the fine bold character of its golden leaves and its almost perpetual blooming habit.

Sambucus nigra aurea is a glorious golden-leaved shrub, free in its growth, and rich in colour, which does not seem to be the least affected by any weather. For planting in groups in telling positions near the margins of woods or plantations, for town gardens, or for ornamenting carriage drives, this is one subject at least that should come into prominent notice.

Yucca flaccida was very striking. It is very dwarf in its habit, and a remarkably free bloomer. Every plant here had one or more fine spikes of white flowers. Amongst *Campanulas*, *C. turbinata pallida* is worthy of remark as a very good thing. A bed of *Violas* also made a brilliant show. This flower has done much better than usual with us in the South this season. The plants are green and vigorous, and flowering with great freedom at a time when they are usually almost burnt up. A variety named Blue Bell has a free dense habit of growth, is wonderfully floriferous, and stands well, and amongst whites none do so well, or give such great satisfaction here as *Purity*, which, like the first-named, is a grand bedder. What is this *Tritoma* with such gigantic flower-stems? *Tritoma grandis*, the tallest and finest of the genus, sometimes throwing a strong, sturdy spike to the height of 7 feet, but usually about 6 feet. It is a very continuous bloomer from this time onwards into January, should the weather be not too severe.

Amongst *Roses* there is nothing special to note, except it be that *La France*, on its own roots, is very fine. It does exceedingly well here, and throws splendid blooms.

One of the most striking flowering plants in the nursery is *Lythrum roseum superbum*, whose spikes of richly coloured flowers stand out well everywhere, and at first sight recall the beautiful *Orchis foliosa*, which it much resembles. A truly beautiful plant is this, common though it be. In *Rudbeckia Neumannii* we have one of the brightest of garden ornaments. It will soon be flowering in quantity, and will be found an exceedingly effective plant for border or pot culture.

It grows to the height of from 2½ to 3 feet, and produces its rich orange-yellow flowers in great profusion. A beautiful free-flowering ornamental tree will be found in *Robinia Pseud-Acacia semperflorans*. It is a free grower, very ornamental, and keeps on producing its racemes of white flowers for a considerable time.

Amongst curious plants the singular *Menziesia polifolia bicolor* must always hold a conspicuous place, as much for the beauty of the purple, white, and striped flowers as for the singularity of their production on the same plant. Another odd-looking but very interesting plant is the white *Monkshood*, *Aconitum album*, flowering in the mixed border here for the first time. It is a scarce plant though by no means new, having been introduced from the Levant in 1752. One of the showiest of hardy biennials is the splendid pale yellow-flowered *Carolinian Coreopsis lanceolata*, and it is a very free bloomer. In *Harpalum rigidum* we have an herbaceous plant of the first water. It is neat and stately in its growth, and wonderfully floriferous from July till October, the flowers measuring from 4 to 5 inches across, and bright orange-yellow in colour, with a light brown centre. For planting in masses or for brightening up the mixed border, *Harpalum rigidum* will be found a plant of great merit.

Mr. Parker's nursery is especially rich in aquatic and bog plants, and wealthy indeed as regards that delightful plant, *Aponogeton distachyon*, which nowhere have we seen in finer condition than here. The well-known pond has this season been embanked, and the contents rearranged, so that all are seen to better advantage now. In addition to the *Aponogeton* we noted the beautiful white *Nymphæa tuberosa*, not so straggling in its growth as *N. alba*; *Lythrum roseum superbum*, as good as an aquatic as in the borders; *Villarsia nymphæoides*, very pretty and interesting, the segments of the straw-coloured flowers being delicately fringed; *Menyanthes trifoliata*, a good native summer-flowering plant; the *Water Soldier*, *Stratiotes aloides*, a peculiar floating or rather submerged plant, somewhat resembling a *Bromeliad* in habit, and which used to be found in the ponds on *Wandsworth Common*; *Hydrocharis morsus rance*, the *Frog-bit*; the *Water Violet*, *Hottonia palustris*, an elegant little plant, resembling some of the mosses in its habit of growth, and bearing spikes of delicate pink flowers; *Equisetum filiforme*, a very distinct plant, by reason of its well-defined black-banded nodes; *Typha stenophylla*, with its narrow leaves and singularly curious interrupted flower-spike; *Limncharis Humboldtii*, a beautiful yellow aquatic, usually treated to the temperature of a stove, but which has been out two winters in this pond without being injured; and *Nuphar adveoa*, a distinct plant from its congeners, inasmuch that its leaves stand well out of the water, and so have a more imposing effect.

Arrangements have been made to test the hardness of various swamp plants, and it may be recorded that *Sarracenia purpurea* stood out all last winter in the new bed, and looks none the worse for it. Near by was a thriving specimen of *Lobelia siphilitica*, an old Virginian species, remarkable for its neat branching habit, and fine deep blue colour; and *Acæa novæ-zeelandiæ*, a perfectly hardy peculiar little plant, for which the margin of a pond would be a very appropriate position.

Amongst trees and shrubs, the more choice things that came under our notice were the remarkably handsome double pink-flowered *Rubus fruticosus roseo-plenus*, one of the very finest pillar plants in cultivation. It grows with extraordinary freedom, and flowers with a vigour that is truly remarkable. *Robinia Pseud-Acacia monophylla* is very distinct, while the beauty of *Virgilia lutea* needs only to be mentioned. *Acer Negundo variegatum* is becoming well known and freely planted now. What a striking object this is by moonlight! *Hypericum proliferum* is a very fine yellow-flowered shrub; and after seeing the fine specimen of *Euonymus radicans variegatus latifolius* growing against Mr. Parker's house, we can strongly recommend it for clothing walls. There are two varieties of this plant in cultivation. This is the major variety, having the broader and bolder leaves of the two. It is a splendid wall-clother. In the *Carolina Poplar*, *Populus angulata*, we have a variety with enormous heart-shaped leaves, which in a young state will prove of great service in the sub-tropical garden. *Ceanothus azureus grandiflorus*, is an exceedingly floriferous plant, and the finest of the genus. The golden variegated *Balsam Poplar* also makes a beautiful tree; and passing to a more lowly subject we have in an

arborescent form of *Hedera Helix aurea*, a bushy, golden-leaved Ivy, of rare beauty. That beautiful white flowered shrub, *Olearia Hastii*, we noted as flowering very freely in a small state. *Wistaria japonica* is a very distinct and thoroughly good wall or pillar plant. It is a good grower, and flowers with much greater freedom than *W. sinensis*, though the panicles of flowers are not so long as in that variety. It has seeded here for the first time this season, and its club-shaped, woolly pods are by no means the least ornamental feature in the plant. Besides the *Ceanothus* previously mentioned, we may allude to *C. Arnoldi* as a free-flowering and perfectly hardy shrub, with pale blue blossoms. *C. Gloire de Versailles* and *C. spectabilis roseus* are also very pretty varieties.

We also remarked here several varieties of the American Blackberries, which deserve much more attention than they get at present. One of the best of all is the *Lawton*, a most prolific bearer of large, jet-black and finely-flavoured berries. The black fruits of the *Kittatinne* are also of fine quality, and as large as *Mulberries*. The *Dorchester* variety may also be mentioned as being amongst the best.

Home Correspondence.

Three Days' Shows.—The great shows of the current year having passed away, the framing of new schedules for 1878 will soon occupy the attention of secretaries, indeed one or two are already in print, and as three days' shows which terminate on Saturdays seem to be the order of the day, permit me to draw the attention of the promoters to the great loss, inconvenience, and sacrifice which attend this arrangement, and to inquire if nothing can be done to relieve distant exhibitors, who are obliged to pack and travel the day before the shows open to the public, and cannot by any possible chance return before the following Monday. To make large shows pay, I am well aware that they must be attended by the masses, and we are told that Saturdays are the only paying days; but, judging from appearances, I am inclined to think the majority of the visitors could have attended the September shows equally well earlier in the week when owners of valuable plants might have reached home with their treasures on Saturday, and exhibitors of fruit would have been able to remove their produce while fit for use. When I state that the three great September shows this year represented in my case seventeen days' absence from home, including three Sundays, I feel sure that the hard-working secretaries, to whom we are indebted for every facility and accommodation, will admit that we have a grievance, and as distant exhibitors cannot be dispensed with, I trust they will endeavour to make arrangements that will admit of our getting home before the Sunday. If this cannot be done it is more than probable that many exhibitors of valuable plants and perishable fruit will be conspicuous by their absence. Another inconvenience and annoyance with which exhibitors have to contend is the way in which the public are allowed to elbow and impede them when they commence packing up after the show is over. When I was at the Alexandra Palace I discovered that the majority of the exhibitors, distant and local, were strongly opposed to Saturday night terminations; but no one seems to have taken up the matter, and as societies may be living under the happy delusion that horticulturists are perfectly satisfied with their arrangements, kindly favour me with space for these lines at your earliest convenience, and assist in working out a system of holding shows which will tend to the advancement of horticulture by making the interests of promoters and producers mutual. *W. Coleman.* [We have received other complaints of like nature with reference to the proposed provincial show at Preston next year. Eds.]

How to Keep Nuts.—Thinking that a few remarks as to the best way, according to my experience, of keeping Nuts *à propos* just now—the time of ingathering—I will briefly lay before the readers of the *Gardeners' Chronicle* the *modus operandi* practised here, and which is very simple, but nevertheless effective, and answers the purpose for which it has been made admirably. In the east portion of a south and east angle border, and under the shelter of a wall of the

same angle, are our "Nut vaults." They are made with dry bricks placed closely together to prevent the mice from getting through, 20 inches deep, 3 inches from the surface, to leave room for covering material, and 18 inches wide at the bottom, and about 20 at top. In these vaults are placed pots corresponding in size with the vaults, having their drainage holes stopped, and into these pots are put the nuts, leaving them in their husks, in which they keep better. They are of course put into the pots in a dry state, and as the pots are being filled a sprinkling of salt can be applied with advantage to the keeping quality of the nuts. When the pots are filled they are covered with slates overlapping each other and with the ends resting upon the side walls of the vaults; then over the slates $1\frac{1}{2}$ inch Oak board about the same size as the slates, so that they can be easily removed; after which the whole is covered with a couple of inches of soil, and, in doing so, making it correspond with the other portion of the border, which has a slope of about half an inch in the foot. This done, there remains nothing more to be done except the taking out of the Nuts as they are required—say sufficient for three or four days at a time—which can be easily done by removing a little of the soil from the first two boards and the slate, immediately replacing them, taking care not to let any of the soil fall into the pots in doing so. To those gardeners who either harvest or buy a quantity of Nuts or Filberts, and which they wish to keep satisfactorily through the winter and spring months, I would say, "Try the above." *H. W. Ward, Longford Castle.*

White Blackberries (p. 439).—The white Blackberry is not a new plant. I had a large bush of it some years ago. The fruit was pretty and abundant, but the bush became too straggling and I destroyed it. *Henry N. Ellacombe, Eaton Vicarage, Oct. 8.*

Pan-Culture of the Watercress.—In your report on my pans of Cresses (p. 442) you say "the first cutting will be ready in about six weeks." Permit me to say that the time that must elapse between putting in the cuttings and taking the first supply for the table varies with the season and the conditions. From May to the end of September twenty days will suffice to fill the pans, and allow of a plentiful gathering. In the middle of April last we started some pans on the floor of a Pelargonium-house. The cuttings were well rooted in three days, and the pans were then put on the stage, to benefit by the sunshine. From those pans we cut Cresses for table of the finest quality in fifteen days from the time the cuttings were inserted. The weather happened to be very favourable, or another five days would have been required. I hear that many have failed in their attempts to grow Watercresses in this quick and simple way, and I suspect the cause of failure is the use of large instead of small cuttings, and perhaps the want of a little careful nursing in the first instance. The pans I showed at South Kensington had been cut from for six weeks. *Shirley Hibberd.*

Ampelopsis Veitchii.—I regard the changeable character of this creeper as one of its principal merits, adding much to its interest and value, for were it evergreen it would be without one of its principal charms—the rich blending of colour in the leaf that renders it so exceedingly attractive at this season of the year. One great objection to most creepers on houses is their loose straggling habit, necessitating almost constant attention and the use of nails or other means of support to keep them tidy and in proper trim, but the grip of *Ampelopsis Veitchii* is so secure as not to require the slightest assistance, be the position ever so exposed. Planted in poor sandy soil I know of nothing more ornamental or desirable to climb up the light brick walls of dwellings or to use alternately with any of the small-leaved variegated *Ivies* such as *marginata rubra*, which associates well with it and assists in showing up the beauties of the *Ampelopsis* to great advantage. To have the best effect it is possible to produce, they should be kept in distinct panels, which may easily be done by cutting away any shoots likely to encroach beyond the space allotted. There are many hot-looking fronts and gable-ends of houses that might be clothed and adorned in this manner instead of being disfigured by straggling *Roses* covered with mildew or greenfly, and dragging out a miserable existence. Much as I admire the *Rose* I do not think hot dry walls the proper place on which to train them, or to see them to advantage, and the climbing section never look so well as when they can ramble at their own sweet will without training or restraint of any kind. *F. S.*

I was much struck with this beautiful climber when on a recent visit to Strafford House, Strafford, County Kildare, the beautiful seat of the Hon. Mrs. Barton. It is covering a wall here 15 feet high and as much in breadth. The beautiful tints of the foliage render it one of the most beautiful of deciduous climbers. I enclose some of the leaves and shoots for your inspection. [They were richly coloured. *Eds.*] *Mr. Bedford, the intelligent*

gardener here, intends planting it largely, for as seen with him it is really an object of very great beauty. It clings to the walls and cement of its own accord, therefore requires no nailing. Clematises also grow out-of-doors here, and are very fine, producing a profusion of flowers when there is a scarcity elsewhere. *A. Outram.*

Removing East Lothian Stocks in Flower.—We have this autumn succeeded in removing a considerable quantity of the above most useful and ornamental plants, when they were full grown and with quite a show of flowers, from medley borders to a terrace, where, for certain reasons, it was necessary to make a show, which was neither anticipated nor provided for earlier in the season. The origin of such an idea at a time so apparently inopportune was more the result of necessity than anything else; there was no other alternative left for us besides risking the East Lothians or assuming the wintery attire of evergreen shrubs six weeks before the proper time. Finally we concluded that the chance to win or lose was worth the venture. We had excellent stubby, well-grown plants, not overcrowded, to select from, and we were further fortunate in having the plants planted in a soil of a heavy, holding texture. The success attending such an operation seemed to rest mainly on the size of the ball of earth that could be removed intact with the plants, so that we exercised every care in lifting to cut all round the plant in the first place, and we were equally careful to take every individual plant on a spade direct to its destination without further tossing about. The process was no doubt a slow one, as it was found impracticable to take more than four spades on a hand-barrow at a time—the hand-barrow being considered the only safe means of locomotion; and yet it is surprising the quantity of plants that two careful men will remove in a day within convenient distance. In planting the hole was made large enough to receive each ball of earth without risk of breakage, and a dew overhead night and morning was all the further trouble that was necessary to secure the object we had in view. We used a thin shade during strong blinks of sun for an hour or so, and to-day (October 8) the beds are one glowing mass of scarlet, purple, and white, alternately arranged, and he would have a keen eye indeed who could tell that the plants were only taken there three or four weeks ago, the only traces of removal being a few yellow leaves at the bottom of each plant. The success of even such a small scheme as this is sometimes of importance after such a fearful season. With plenty of material in hand many an eyesore might be erased, and many a gloomy spot in conspicuous places made bright. It only requires a little forethought, and the will to carry it out. He is supposed to be a bad general who cannot plan and counter-plan, and perhaps the past season has offered more scope and compelled more "scheming" than any of its predecessors for a long time past. It may be useful to those for whom these hints are intended to add that our seed was sown in a cold frame early in March, and transplanted in due course, and never "coddled." Many a failure that is wrongly ascribed to other causes is the result of sowing the seed too late in the season. *W. Hinds.*

Pumpkin Preserve.—Your correspondent, Mr. A. Dean, is wrong in his surmise as to the Gourd I grow and recommend for making preserve being the Ohio Squash. Instead of being egg-shaped, as he describes that variety to be, it is round, and as rich and handsome looking as a Melon, and when grown on a rubbish-heap or in rich vegetable soil often attains to such a size as to weigh from 100 lb. to 150 lb. I have several now that are not far short of this, one of which I shall have great pleasure in sending Mr. Dean if he would like to have it, or a good supply of seed if he prefers that instead. I think he will find this Gourd far superior to any of the Marrows, all of which, however, are good, and of special value this year now that fruit is so scarce and dear. About here the poor use them in pies with a few Raisins or sour Apples, with either of which they are very palatable and wholesome. It would be well if the growth of them could be more encouraged and people taught how to turn them to the best account, and this was my object in writing about the matter, as I thought the present season a favourable one to bring them under notice. *S. W.*

The Flow of the Sap.—Your correspondent "A." somewhat misapprehends my reference to a possible clogging of the sap cells of the tree as probably producing the gradual decadence in the growth to which he refers. If the sap, as I assume, does ascend through what "A." terms the vascular wood and returns through the bark, it is evident that the clogging must commence immediately above the ring made by the severed bark. Then, as the vessels become choked for lacking outlet for the sap, the ascending action of the sap must become less and less vigorous, until at length there is no further room available for more of the upward fluid; in fact, the

tree or branch would become asphyxiated or choked by its own current of blood. This is but a guess, perhaps a wild one, but it has, at least, the merit of seeming to be correct. *D.*

The Late Potato Show at the Aquarium.—After the treatment the promoters of the recent Potato show received at the hands of the manager, Mr. Wybrow Robertson, it is scarcely probable that they will again honour that place of amusement with their presence. It transpired that during the performances that were taking place on the stage in the afternoon and evening for an hour and a half each period of the day, the Manager had all visitors and exhibitors excluded from the front portion of the Potato show. This matter did not come under the special notice of any members of the committee until the afternoon of the last day, when several, including the Hon. Secretary, M. Henry Vilmorin of Paris, and other gentlemen, were hustled out of the place. This violation of the agreement made with the committee naturally excited the ire of some members, and Mr. Robertson having been found, was bluntly told that it was a breach of faith, both to the subscribers and the public, thus to exclude them from the Potato show. Mr. McKinlay set Mr. Robertson and the police at defiance by getting under the tables into the allotted space, and the officials thought better than to remove him! Mr. Robertson endeavoured to palliate his conduct by stating that the public would have climbed upon the tables to see the performance, and thus have damaged the Potatos; but there was no ground for this assertion, as the public in the gallery at the time were chiefly persons of Potato tastes, and further, the placing of a length of baize along the top of the gallery rail would at once have completely shut the merry-Andrew business from view. The truth must be told. It was the manager's desire, by excluding the public from the gallery, to force them into the reserved seats below, for which an additional charge was made. The Potato men have had enough of the manager and the Royal Aquarium courtesies; they will in the future be careful that they place themselves in the hands of gentlemen only. *A. Committeeman.*

I have read with much interest your account of the great Potato exhibition, and regret I had not the opportunity of inspecting the grand display of the really useful root, for such exhibitions must be of immense importance, and do a great service to the community, whose health and comfort are so much helped or hindered by a liberal supply of good Potatos. I think there is more attention given to the cultivation of this root than ever there was, and I know there are much better kinds now grown than formerly, and I observe in the local shows called "cottagers' shows" that the working men are fully aware of the importance of growing the very best sorts that they can procure. At some of these very small shows I have seen (this very unfavourable season) a very creditable sample of tubers, apparently perfectly healthy, but the results obtained by different people in respect to the quantity and quality is very conflicting and confusing. One gentleman here grew the Snowflake, and was delighted with his success in every way. The quality was very superior, but in a few days the crop was rotten with disease, while others who grew the same sort in adjoining gardens had no disease. The Rector of Woodstock produced with us an excellent crop, and resisted the disease, while others of great name, growing under the same conditions, were entirely lost. But there is one point which seems to have escaped the notice of schedule-makers which seems to me to be of great importance in forming a sure and reliable test of the quality of the Potato, and that is by having samples cooked and submitted to the judges in that state. I officiated as judge recently where we had several dishes submitted to us, and they were well cooked—done to perfection—a thing seldom seen in our large hotels, &c., where the very best Potatos are spoiled by cooking. I think that while the man who produces the best tubers is deserving of thanks, the cook who can do her part in the culinary department also deserves honourable and substantial reward. *William Payne, Edmont, Taunton.*

Strawberries.—Three years ago I excavated to the depth of 4 feet a large plot of ground. I had several large cartloads of rubbish, consisting of cuttings of plantations and hedges, cast into this pit. The whole of the soil was then thrown on to the top of this rubbish, the good soil being kept uppermost. Strawberries were planted on this raised bed and were allowed to grow in a mass; last year we grew on this bed, or a series of beds, the largest crop we have ever grown. Two years since I excavated another large plot, to the depth of 5 feet, throwing in rubbish and treating it in the same way as the last one. The plants are now most luxuriant. I ordered that several beds of Strawberries, which were to have been dug up this autumn, be preserved: I had them heavily manured; the beds are now a mass of plants, and these are to remain as they are—the leaves not only keep the beds

moist, but they exclude frost from the crowns. Another plan I have tried this autumn. I have had all the old plants of a bed five years old transplanted on fresh deeply trenched ground, well manured. The plants are looking very vigorous, and the crowns are well developed. I think it is the soil which gets exhausted, not the plants. Again, I had all the plants which had been forced last spring re-potted, the exhausted earth having been knocked off, and fresh loam, mixed with soil from a cesspool, put in its place. These plants are now specimens of vigour, the crowns much more developed than at this time last year, or in fact at any time during their former growth: the pots are 12 inches in diameter. *Observer.*

Eucharis.—We have at present a double row of *Eucharis amazonica* on a stage in front of our conservatory which is between 50 feet and 60 feet long. One row of the *Eucharis* are in 15-inch pots, the other in 6-inch and 9-inch. With a few *Dracena terminalis* amongst them the effect is very striking. Some of the 6-inch pots have three flower-stems, and on one of the 15-inch pots there are forty-one flower-stems, with from five to seven flowers on each in different stages. They last a long time either in a moderately warm conservatory or a sitting-room. I shall be very pleased to let any one see them who takes an interest in such things. *Richard Carr, Gr. to F. N. Micklethwait, Esp., Taverham Hall, Norwich.*

Potato Disease.—I am indeed sorry to say that destroying the haulms, as recommended in your last week's number of the *Gardeners' Chronicle*, is powerless to arrest the spread of the fungus, or to prevent the loss of the crop. Immediately I discovered indications of the *Peronospora* this season—in fact, only some half-dozen spots could be detected on the leaves in my small garden crop, the whole looked green and healthy—no finer or healthier could be found in the entire county—I at once mowed down the stems, and burned the entire lot, and when I got up the crop shortly afterwards I did not find three unsound tubers, but in a month afterwards fully two-thirds were decayed, and thrown away to the fowls. I could tell a strange tale about experiments with the *Peronospora*, if I judged it would interest our readers, that would upset many theories so called. *K.*

Agave Corderoyii.—Seeing from the description and figure of *Agave Corderoyii* in the *Gardeners' Chronicle*, that you are desirous of a little information respecting it, I beg to say that I received it of Mr. De Smet, of Ghent, who was the gentleman that named it in my honour. He received a couple of plants from Mexico in 1868, and I enclose his statement to me respecting it. I am very proud of the honour he showed me, as I consider it a very distinct and interesting plant. The plant I then possessed of it I sold to Mr. Peacock, as he was very desirous to obtain it, and probably the one described and figured is the same plant. I have another variety of it, with leaves about 10 inches long, and rather wider, and the spines on the edges not so thick and dark, but the end spine is about the same—1 inch. I have also another, once called *A. C. glauca*, presented to me by the above gentleman, but the leaves are not so erect growing as the in former, but it is a very distinct variety. *Justus Corderoy, Blewbury, Dilcot.*

Reports of Societies.

The Fungus Meeting at Hereford.—The annual meeting of the Woolhope Club for its "Fungus Foray," was appointed for the week beginning Monday, October 1, and ending Saturday, October 6, but a few members of the Society put in an appearance at Hereford as early as September 26. No special work was done by the Club till Monday, but on the previous Thursday Thomas Andrew Knight's "Monarch" orchard was visited at Tillington, his birthplace at Wormsley Grange, and his grave. For a portrait and an account of T. Andrew Knight's work see *Gardeners' Chronicle*, February 10, 1877.

HEREFORD POMOLOGY.

The visit to Wormsley was altogether a pomological excursion, the authorities being Dr. Hogg, Dr. Bull, the Rev. C. H. Bulmer, and an old man from Hereford, 80 years of age, who brought a branch of *Xanthium spinosum* with him, just found close to Hereford. Many of the Apples now growing at Wormsley are hybrids or seedlings, difficult if not impossible to name. The latter part of the Wormsley day was devoted to archaeological and architectural matters, ending with lawn tennis and an excellent dinner at the Rev. C. H. Bulmer's. The Hereford men did not leave Credehill till after 10 P.M., and the 4 miles drive to Hereford was through a thick, white, wet fog, which, though it gave a romantic turn to the drive—it being like riding through the clouds—yet the wet air got sadly into the bronchial tubes of the fungologists, and with anything but pleasant

effects. On Friday the 28th the pomologists visited Holme Lacy to see the wonderful collection of Pears growing upon a south wall, and to see the portrait of Lord Scudamore and Mr. Cornwall. Good gardening was observed in the magnificent growth of the Pears, of *Tropaeolum speciosum*, *Gentiana acaulis*, &c.; together with bad gardening, represented by enormous quantities of diseased Potatoes, allowed to fall into a mass of wet decay upon the surface of the beds. Truffles were turned up from under Laurels. In the afternoon a visit was paid to Breinton to see a famous Foxwhelp Apple tree, but owing to the badness of the season only one Apple could be found, but a Mistletoe plant was observed growing upon the tree with a whorl of three leaves instead of two. At this place a fine specimen of *Polyporus hispidus* was observed on an Ash, but as one side of the ladder always fell off when the top was reached neither ladder nor tree could be ascended: some mischievous person, moreover, had a shot time before shot the *Polyporus*. Fungi are not included amongst the small birds protected by Act of Parliament. Here a small collection of Apples was examined, some with peculiar names, as "Hang Down" and "The Ten Commandments." On asking for an explanation of the latter an Apple was cut in two so as to display ten bundles of vascular tissue very strongly marked (fig. 92). These names were surpassed, however, by the names of others which found their way to Hereford, as "End of the Walk," "Close to the Pump," "Near the Gate," &c. No proper names were known for these Apples, so they took temporary names from their position in the orchard. Saturday was devoted to painting various Herefordshire Apples and Pears, by Miss Ellis, of Hereford, and one of the artists employed on the *Gardeners' Chronicle*. Sunday was spent in a quiet and proper manner, as became the day, the only event of importance being a telegram from M. J. de Seynes, "Professeur agrégé à la Faculté de Médecine de Paris," to say he had just arrived in London with his son, and would be at Hereford on

FIG. 92.—THE "TEN COMMANDMENTS" APPLE.

the following day at 12; to accomplish this he had to leave London at 6 A.M. on Monday. So much for fungological enthusiasm!

THE FUNGUS FORAY.

At last Monday, the 1st of October, and the first day of the "foray," arrived, and with it an influx of fungus men and women and their paraphernalia. M. de Seynes, his son, and Mrs. Chapman, of London, arrived punctually at 12—Mr. Broome, of Bathaston, being in the same train. Later in the day M. Maxime Cornu, of Paris, with Mr. Howse, of Sydenham Hill, were met at the station by Dr. Bull and the Historian of the Woolhope Club. Still later in the evening came Mr. Renny, of London, Mr. and Miss Du Port, of Norfolk, Mr. and Mrs. Bicknell, of London, Mr. Cecil H. Sp. Perceval, of Henbury, the Rev. Mr. Cunningham, from Nottinghamshire, and many others. Dr. George Bennett, Member of the Medical Faculty of the University, Sydney, New South Wales, re-arranged his plans specially to attend the Hereford meeting. M. de Seynes brought with him from Central France some magnificent specimens of the orange-topped *Agaricus caesareus*, the first species in Fries' *Epicrisis*, and the species which, cooked under the direction of Agrippina, poisoned Claudius. None of the Woolhopeans had seen the species before, and it was sketched on the spot. M. Max. Cornu also brought a large number of species of fungi, notably *Agaricus Eryngii*—a parasite upon the roots of *Eryngium campestre*, and never yet detected in this country. Mr. Berkeley could not come, as he was detained by an examination in London; he, however, sent a letter (enclosing two funguses) congratulating the Club on the fine weather. The Rev. J. E. Vize, of Forde, the author of *Æcidium depauperans*, was detained for two days in Montgomeryshire, as two persons in that benighted district had the bad taste to wish to be married during the week of the "foray." Mr. Plowright, the surgeon of King's Lynn, was detained for two days, owing to some "cramming" process, the details of which did not come to light.

Never before were there so many visitors at Here-

ford from long distances, and it was rumoured on apparently good grounds that next year would certainly witness the arrival of the Mikado of Japan, and three botanists from Yokohama, to see if they could not get some hints on fungus-growing better than their present method of producing the "Shu-take" fungus by tapping the "Shu" tree with a mallet. There would be no difficulty with the language, as Dr. Bull speaks all languages (dead and living) with equal fluency. Dr. Bull entertained the visitors from France to dinner, but during his temporary absence no one could remember either the French, Latin, or Greek for "Welsh Rabbit." At this and other dinners the famous Foxwhelp cider was produced; this cider is so strong, that it is hardly safe to open a bottle of it in a dining-room, for the cork rushes out with a terrific explosion. Many bottles burst in the cellars. (Mr. Andrew Knight invented a cold-water cellar to keep the extraordinary potency of this cider within limits by flooding.) It is not uncommon to see scars in ceilings from the percussion of Foxwhelp cider corks, and at one dinner a bottle was opened on the lawn for safety and experiment. In this instance the cork flew out like a rifle-bullet, struck the branch of a tree with terrific violence, and flew off at a tangent into space: it is certain the cork never came down again, and it is probable that at this moment it is sailing through the universe as one atom in the cider-ial system, and is perhaps the new asteroid recently named "Maria" by an American astronomer!

All went to bed very tired on Monday night. Nevertheless, on Tuesday morning the French visitors and a number of old Woolhopeans, including Miss Ellis, were at Dr. Bull's house before 7 in the morning, to snatch a hasty breakfast before starting by the 7.30 A.M. train for Ludlow. All the fungological visitors in Hereford joined this excursion, meeting Messrs. Cooke, Phillips, Lees, &c., either at the Ludlow station or at the Messrs. Forty's house. The excursionists were twenty-three in number. The Messrs. Forty with their customary liberality had prepared an excellent (we were almost writiug luxurious) breakfast for the entire party, and after a stroll through the ancient town the botanists departed in vehicles for Downton Woods. The weather was uncommonly fine, had been uncommonly fine, and remained uncommonly fine until the end of the meeting, so that the visitors from France had no reason in this instance to complain of Perfidious Albion; the only little difficulty rested with one of the Ludlow horses, which proved to be a desperate kicker, and looked round at the Nottinghamshire clergyman (on the box) in a most spiteful manner. Max Cornu carried an immense cylindrical vasculum over his shoulder, a pocket microscope, and a dangerous-looking knife with a blade 9½ inches in length: M. Cornu said the same sort of knife was used for stabbing a French policeman a day or two before. M. De Seynes carried a very small vasculum in front and an instrument half-way between a chisel and a knife, with a blade more than 1 foot long. The first fungus found was the Vegetable "Bifteck," and *Hygrophorus pratensis*, growing in company with *Gentiana campestris*. After these came many of the other well-known rare Herefordshire fungi, as *Cortinarius sanguineus*, *cinnamomeus*, *cinnabarinus*, *Strobilomyces strobilaceus*, *Peziza oenocia*, *Clavaria Botrytis*, *aurca*, *coralloides*; *Agaricus euechrous*, *Hygrophorus calyptiformis*, &c., all large, handsome, rare, and highly-coloured species. The fungi, as regards number, were scarce, but several species, either new or of uncommon interest, were found. By the Teme side we noticed *Scrophularia Ehrharti* and *Iris foetidissima*. One of the Puff-balls, *Lycoperdon gemmatum*, was growing for a considerable distance, up the mossy side of a tree, whilst various species of *Hygrophorus* were growing in plenty in the open spaces, with the "Eye-bright," *Euphrasia officinalis*—"Break-spectacles" in France, said M. Cornu. The find of the day, and new to this country, was undoubtedly *Agaricus Russula*, a crimson-topped *Agaric*, looking exactly like a *Russula* till the gills were examined, and then it proved to be an *Agaricus* "mimicing" the colour and habit of a *Russula*. *Agaricus Russula* was so named by Schæffer, but there is another (book) plant named by the illustrious Fries *Hygrophorus erubescens*; the descriptions of both tally as well as natural objects (especially fungi) will tally with descriptions, and the two plants are undoubtedly the same. According to book descriptions the two things cannot be "co-generic," but those who know the *Agaricus* have never seen the *Hygrophorus*, and those who find the *Hygrophorus* (says M. Cornu) never meet with the *Agaricus*.

There are at least twice as many described species of fungi as there ought to be, especially amongst the small species; a fungus in a dry place is another species in a moist one, on a sunny day it is one thing, on a rainy day another; it may be one thing over night and quite a different species in the morning! A slight alteration in shape, size, colour, odour, or habit of a fungus is quite enough with many fungologists to constitute a new species, and if the species go on increasing in

numbers at the present ratio for a few years longer no one will at length be able to master the plants, or even the literature of a single genus. To merely look over the figures and descriptions of one section of one genus of Peziza in No. 1 of Dr. Cooke's *Monographia* is enough to send an ordinary mortal into a cold sweat. No doubt there are differences, permanent or otherwise, in some of these little red Pezizas, with their little spores and little bases, but we hope the day is not far distant when at least one-half the species will be knocked on the head, to the despair of their founders!

TRUFFLES.

In some parts of the Downton Woods, especially in the open places, there is a luxuriant growth of a common moss, *Molium hornum* (= *Bryum hornum*). Whilst walking over this dense and tall growing moss the quick eye of M. Cornu detected a yellow mycelium known to belong to the singular black, club-shaped fungus termed *Torrubia ophioglossoides*. This *Torrubia* is a parasite upon a spurious sort of underground Truffle named *Elaphomyces muricatus*, and the yellow mycelium (explained M. Cornu) was running over and amongst the moss in search of its underground victim, the Truffle. A careful search just under the surface of the ground in the neighbourhood of the mycelium infested moss soon brought the "Truffle" to light, and in one instance the perfect parasitic *Torrubia* itself was found by Mrs. Chapman. In the search for the *Elaphomyces*, another curious underground fungus came to light, viz., *Cenococ-*

FIG. 93.—FOUR VINEGAR PLANTS IN A BOTTLE OF CIDER.

cum geophilum, and the fact was also observed that mice were searching for and eating the same *Elaphomyces*, so that there was a race between the mycelium of a fungus and mice in search of the same object to prey upon. It is well-known that squirrels and mice are in the habit of searching for, and devouring when found, the Truffles of our markets (*Tuber aestivum*). Truffle-dogs will also eat the Truffles if not carefully watched, as will the trained Truffle-hogs of France.

M. Cornu in referring to the latter animals termed them "learned pigs." Immense quantities of *Agaricus nebularis* were found later in the day; these were often covered with the mycelium which, under favourable circumstances, gives rise to the parasitic *Agaricus Loveianus*. In the moss-house in the woods the Messrs. Forty provided a most sumptuous repast of ham, meat pies, cake, bread and cheese, whisky and champagne. The same gentlemen also provided a substantial tea at Ludlow, so that the fungologists were well refreshed, and all retired tired to Hereford. Mr. Vize (his marriage well over) joined the party in the train.

On Wednesday, October 3, Dinmore was visited as usual; M. Cornu was too tired to accompany the excursionists; Dr. Bull, Dr. Hogg, and some others, remained at Hereford for the committee meeting of the pomological department, and one or two other members remained to examine and sketch the Apples and Pears, and to put the fungi in order. Dr. Bull again entertained the visitors from a distance at dinner, and all adjourned to the Free Library in the evening, where Mrs. Chapman was found still busy sketching. Other members now discussed poisonous fungi; the best and readiest antidotes to fungus poisoning were pronounced to be found in oil and

milk, the latter to prevent the poison laying hold of the coats of the stomach, and brandy to be used as a reviver.

Thursday, October 4, was the "Club day," when the Whitfield lawns were visited, by the kind permission of the Rev. Archer Clive. A larger number of excursionists than usual left Hereford in various vehicles, and horseflesh proved so limited that the Woolhopeans were obliged to enlist for their services two rank jibbers and four jet-black undertaker's horses with flowing manes, long tails, and a funereal trot. Amongst the fungi found may be mentioned one of the true Truffles, *Tuber puberulum*, *Agaricus dryinus*, *Cantharellus tubiformis*, *Peziza arguinosa* in abundance, *Russula Queletii*, *Clavaria cinerea*, *Hygrophorus chrysdon*, *Helvella elastica*, and *Stemonites fusca*. On leaving Mr. Archer Clive had kindly prepared a good luncheon for such as cared to partake of it.

THE DINNER.

There were seventy-one Woolhopeans at the "Green Dragon" dinner, and the *menu* (see p. 461, fig. 90), prepared by the artist-in-ordinary to the Club, shows the nature of the repast set before the guests. *Craterellus cornucopioides* was a highly relished novelty, cooked in honour of M. Cornu. This fungus, when prepared for the table, has a somewhat singular appearance, being jet-black in colour, and in this resembling burnt Onions. Its odour is highly inviting, and its taste truly delicious.

After dinner Dr. Bull gave a report of the progress of mycology during the year. In this report he touched on all the new work done by fungologists since last autumn, and pleasantly referred at some length, in the French language, to the visitors from France and their works, so well known and appreciated in this country. In happy and well selected terms he bade them a hearty welcome to the Woolhope meeting, and then again breaking off into English he gave a welcome to Dr. Bennett, of New South Wales, who was at the head of the table. Dr. Bull's speech was followed by some remarks (also in French) from Dr. Steele, of Abergavenny. This speech, by its fluency and pleasant allusions, took the room by storm, and was replied to, first by M. de Seynes, and then by M. Maxime Cornu. Both gentlemen expressed themselves delighted with this, their first visit to England, and with the generous and hearty welcome they had received at Hereford and elsewhere. They said how pleased they had felt to meet so many English botanists, and how the different societies of France were arranging fungus gatherings after the exact manner of the Woolhope Club. The Rev. C. H. Bulmer then read a report on the progress of the forthcoming new illustrated work to be named *The Herefordshire Pomona*, in which work it is proposed to give life-size coloured figures of all the best Apples and Pears grown in Herefordshire. The last paper at the "Green Dragon" was a humorous one by Dr. Cooke, termed "What is the Use of Fungus Hunting?"

THE SOIRÉE.

At 8 o'clock a *soirée*, attended by a large number of botanists, was held in the house of Thomas Cam, Esq. Here microscopes with high powers were ready, and serious work was commenced. M. Maxime Cornu described at some length, in the French language, a disease of the Vine named "Anthraxose," observed in the environs of Narbonne; the description was accompanied by a series of beautifully-executed drawings. The same gentleman exhibited highly-finished drawings of new *Agaricus* and other fungi. The next paper (by the writer of this report) was on a fossil *Peronospora* from the scalariform axis of a *Lepidodendron* from the Coal Measures. The fungus, therefore, existed during the Palæozoic epoch. One of the remarkable points in the plant exhibited was that the zoospores could be seen under the microscope still *in situ*, and another point of interest was that these zoospores, and indeed the other parts of the parasite exactly agreed in size and habit with the similar bodies found in the fungus of the Potato disease at the present day. The paper was illustrated by enlarged drawings, and the actual specimens were exhibited under the microscope. This extremely ancient fungus is now named *Peronosporites antiquarius*, and it will be illustrated in an early number of the *Gardeners' Chronicle*. The writer of this also exhibited a singular growth of *Penicillium glaucum* at the bottom of a bottle of Calocine.

The Rev. J. E. Vize then read some notes on a singular development of the spores of *Puccinia Conii*, illustrated by drawings and specimens. This paper was followed by one from Dr. Cooke on the *Myxomycetes*, and some notes by Mr. Phillips on *Pezize*. Time would not permit of reading the Rev. Augustin Ley's paper on the Mosses of Herefordshire, which all regretted, though it was nearly midnight when the last of the visitors left Mr. Cam's house.

ANOTHER EXCURSION.

Friday, October 5, was devoted to an exploration of Lyonshall Wood and neighbourhood, near Titley.

Amongst notable plants found here may be mentioned *Uredo vacciniorum*, *Puccinia veronicarum*, *Nyctalis parasitica*, *N. asterophora*, *Ptychogaster albus*, *Lactarius glycosmus*, *Agaricus vaccinii*, and many other rarities too numerous to mention. The Rev. J. E. Vize lighted on *Poronia punctata* growing on a discarded fragment of a rustic's corduroy breeches. After this district had been well searched the Woolhopeans drove direct to Moor Court, where they were most hospitably received by the Rev. James and Mrs. Davies. Here an excellent dinner had been prepared, and over this dinner till dark the fungus men discussed fungus subjects in a variety of languages. French was probably most pronounced, often mixed with English; when both failed Latin came to the rescue, with sometimes a touch of Greek—when all languages fell short of a clear meaning, drawing as a last resource was resorted to. As an example, no one at our end of the table could remember the French for Cranberry-pie, whereas *Vaccinium Oxycoccus*-pie was common to all! And so, with many thanks to the kind host and hostess the party drove off in the black darkness of evening to the Titley station. Owing to the nature of the vehicles and the quality of the quad-rupeds, the party was late at the station, but such is the respect with which fungus-men are held in Herefordshire that the station authorities detained the train for six minutes till the arrival of the party.

ODDS AND ENDS.

Amongst objects of interest in the Woolhope room may be mentioned four singular Vinegar-plants (what once was) a bottle of cider (fig. 93). They were overlooked till the last moment, as every one took them

FIG. 94.—A TWIG EMBRACED AND HELD TIGHT BY THE INCURRED EDGE OF A FUNGUS.

to be four tracheæ or wind-pipes, or something of the sort, in spirit, belonging to one of the doctors of medicine present. The true explanation of the singular growth is probably as follows:—A small Vinegar-plant at first grew on the top of the cider in the neck of the bottle, and as layer on layer got formed the plant took the shape of the neck of the bottle till it got heavy and dropped to the bottom in the form of a wind-pipe. When the first plant had fallen down another got formed and dropped away for a third, till at last all the four perfect plants were free in the liquid. Another singular growth was shown in a plant of *Craterellus cornucopioides*, in which a curious lip-like growth on the edge had embraced a branch and carried it up in a tight fold, reminding one of Mr. Darwin's observations on the leaf of *Pinguicula*. Had the twig been a slug, a crane-fly, or a worm, we should have had an imitation of "carnivorous fungus" at once. Mr. Berkeley sent for exhibition *Cantharellus cinereus* and *Craterellus sinuosus*. It will be observed how much alike in sound the generic names are. Unfortunately for the two genera, certain species belonging to one or other are also so much alike in character and habit, that it is almost impossible to refer them with certainty to one or the other: and to make matters worse, the *Craterellus* of one book is often the *Cantharellus* of another. Mr. English, of Epping, sent *Sistotrema confluentis*, *Thelephora multizonata*, cristata, and sebacea; on the table we noticed *Lenzites sepiaria*, *Polyporus nummularius*, *P. Schweinitzii*, *P. ribes*, *P. sanguineus* from South America (Mr. Percival), *Cynophallus caninus*, *Peziza auricolor*, *P. corium*, a large, handsome, jet-black plant, brought from King's Lynn by Mr. Plowright; *Agaricus phlebophorus*, *A. inamæus*, *Lycoperdon saccatum*, *Thelephora caryophyllæa*, and many others. As

regards hybridism and cross species in fungi, it is worthy of note that a plant was exhibited exactly intermediate between Helvella lacunosa and H. crispa, the plant in question had the black and somewhat plain pileus of the former, and the larger growth and snow-white deeply ribbed and hollow stem of the latter. As regards the fungus of the Potato disease Mr. Broome stated that he had repeated his experiment this year with Potato leaves infected by the Peronospora by placing them in water: in a week's time the leaves were again completely filled with resting-spores. Mr. Bicknell mentioned a curious fact in regard to Boletus scaber, he stated that he had recently seen about 10,000 specimens growing in groups or masses all within a quarter of a square mile on Cray Common, near Chiselhurst: it is usual to see the plant in single specimens only. There was an exhibition of Apples and Pears at the same time with the fungi, and the specimens were so numerous that they filled a second room down-stairs, and some were even placed upon the floor; there were more than 3000 specimens exhibited.

All the fungus men met at Dr. Bull's house for the last time on Friday evening, October 5, when M. Maxime Cornu exhibited a series of drawings and plates (at present unpublished), illustrative of the life history of the Phylloxera and its ravages upon the Vine. M. Cornu explained the illustrations in detail, and all present agreed that the drawings were the most highly finished, elaborate, and exhaustive illustrations they had ever seen. Dr. Cooke exhibited drawings of Agarics and some of the larger fungi; Mr. Chapman showed a series of boldly executed and richly coloured drawings of fungi, many having been made in France and Switzerland; and the writer showed a drawing of Agaricus campestris, with traces of a volva.

FAREWELL!

The French visitors and some others left Hereford by an early train on Saturday, several Woolhopeans being on the platform to see them off, and by mid-day all the fungus visitors had left the place. The 1877 meeting was the tenth, and though fungus had been uncommonly scarce in numbers all through the autumn, yet the 1877 meeting will always be remembered as in every way the most pleasant and successful of the entire series, on account of the additions made to the flora, the importance and oneness of the papers read, and the thoroughly enjoyable nature of the excursions and meetings. W. G. Smith.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, OCT. 10, 1877.

Table with columns: MONTH AND DAY, BAROMETER, TEMPERATURE OF THE AIR (Highest, Lowest, Range, Mean for 18 years, Dew Point, Degree of Humidity), WIND (Average Direction), RAINFALL. Data for Oct 1-10 and a Mean row.

- Oct. 4.—A fine day, but cloudy and very cold. Fog in morning.
5.—A very fine bright day. Cold.
6.—A brilliantly fine clear day.
7.—A dull cold day. Foggy and misty. Little rain fell at 11 p.m.
8.—A fine day, cloudy and strong wind. Little rain fell in early morning. (Great fall of leaves.)
9.—A fine day, partially cloudy. Cold.
10.—Overcast, dull day. Very cold.

LONDON: Barometer.—During the week ending Saturday, October 6, in the vicinity of London the reading of the barometer at the level of the sea decreased from 30.21 inches at the beginning of the week to 30.01 inches by the evening of October 2, increased to 30.67 inches by the morning of the 6th, and was 30.63 inches by the end of the week. The mean reading for the week at sea level was 30.25 inches, being 0.05 inch above that of the preceding week, and 0.38 inch above the average.

Temperature.—The highest temperatures of the air observed by day varied from 64.1° on the 6th to

57° on the 4th; the mean value for the week was 62°. The lowest temperatures of the air observed by night ranged from 34° on the 4th to 43° on the 1st; the mean for the week was 38.7°. The mean daily range of temperature in the week was 23.1°, the greatest range in the day was 26°, on the 5th, and the least 18.1°, on the 1st.

The mean daily temperatures of the air were as follows:—September 30, 50°; October 1, 50°; 2, 49°; 3, 46°; 4, 44°; 5, 50°; 6, 50°; 7, 50°; and the departures in defect of their respective averages were 4°; 3°; 3°; 7°; 5°; 2°; 7°; 3°; 8°; 8°; 3°; 2°, and 2°; 9°. The mean temperature of the air for the week was 48°; 7, being 5°; 1 below the average of sixty years' observations.

From September 16 to the present time the weather has been exceedingly cold, and the mean daily temperatures have been all below their averages to the mean amount of 5°; 2; on September 25 the deficiency amounted to 10°; 7, and on October 4 to 8°; 8.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 118.1° on the 5th, 123.3° on the 6th, 113° on the 2d, and 111° on the 1st; on the 4th the reading did not rise above 99.3°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 25.1° on the 4th of October, 26.1° on the 6th, 28° on the 5th, and 28.1° on the 3d. The mean of the seven low readings was 29°.

Wind.—The direction of the wind was N.E., and its strength very light. The weather during the week was fine and bright, very dry and cold. No rain fell. Fog prevailed on the 1st, 2d, 3d, and 4th of October, and a solar halo was seen on the afternoon of the 6th inst.

ENGLAND: Temperature.—The highest temperatures of the air observed by day were 68° at Truro, 65.3° at both Cambridge and Eccles, and 64.3° at Blackheath; the highest temperature of the air at Hull was 58°, and at Wolverhampton 59.3°; the mean value from all stations was 62.1°. The lowest temperatures of the air observed by night were 29.3° at Cambridge, 31° at both Wolverhampton and Nottingham, and 33.1° at Bristol; the lowest temperature of the air at Portsmouth and Sunderland was 43°; the general mean from all stations was 36.1°. The range of temperature in the week was the greatest at Cambridge, 36°, and the least at Sunderland, 18°; the mean range from all stations was 25.3°. The mean of the seven high day temperatures was the highest at Truro, 64.3°, and at Cambridge 63°, and the lowest at Bradford, 56.1°; the mean value for the week from all stations was 60°. The mean of the seven low night temperatures was the lowest at Nottingham, 35.1°, and at Wolverhampton 36°, and the highest at Truro and Sunderland, both 46.1°; the mean from all stations was 40.3°. The mean daily range of temperature in the week was the least at Sunderland, 12.1°, and the greatest at Cambridge, 28.1°; the mean daily range from all stations was 19.1°.

The mean temperature of the air for the week from all stations was 49.1°, being 6.3° lower than the value for the corresponding week in 1876. The highest was 54.3° at Truro, and the lowest 47.1°, at Nottingham, Sheffield, and Hull. The weather during the week was fine, bright, very dry, and cold. At Plymouth and Truro one-tenth of an inch of rain fell, but at other places scarcely any rain was measured. The average fall over the country was 0.01 inch. Fog was prevalent during the week. A solar halo was seen at Bristol on the 6th inst.

SCOTLAND: Temperature.—The highest temperatures of the air varied from 64° at Dundee to 59° at Leith; the mean value from all stations was 61.1°. The lowest temperatures of the air ranged from 33° at Perth to 42° at Greenock; the mean from all stations was 38.1°. The mean range of temperature in the week from all stations was 23.1°.

The mean temperature of the air for the week from all stations was 51°, being 1.1° lower than the value for the corresponding week in 1876. The highest was at Glasgow, Dundee, and Aberdeen, all 52°, and the lowest at Leith, 49.1°.

Rain.—The fall of rain at Greenock was 0.26 inch, and at Aberdeen was 0.05 inch; at Glasgow, Edinburgh, Dundee, Paisley, Leith, Perth, no rain fell; the mean average fall over the country was 0.04 inch.

DUBLIN.—The highest temperature was 68.1°, the lowest 36.1°, the range was 31.1°, the mean 53.1°, and no rain fell.

JAMES GLAISHER.

Obituary.

We regret to hear of the death lately, at Nursery House, Broughty Ferry, N.B., of JOHN STEWART, Esq., in the eighty-second year of his age. Mr. Stewart was the senior partner of the well-known nursery firm of John Stewart & Sons, of Dundee.

Enquiries.

He that questioneth much shall learn much.—BACON.

210. ERIOPSIS.—I bought a plant of the above (with peculiar long, rough, purplish bulbs), which proved to be in bad health, and there is now only an atom living. Mr. B. S. Williams says E. biloba requires cool treatment, sunshine, and plenty of water. The Botanical Magazine says E. rutilobulbon (also rutilubon) was found on the trunk of a Palm; and Burbidge (Cool Orchids, &c.) says that both names are of one species, which grows on the margin of streams, even sending down its roots into the water (!). Please advise on the above. T. T. [We have no experience. What do our correspondents say? Eds.]

Answers to Correspondents.

BEGONIAS: T. T. Your Begonia argyrostigma is losing its leaves from not being kept sufficiently warm, and possibly too wet at the root. It is a stove plant.

BOOKS: E. W. The pamphlet, Stock and Share Investments, is published at the Bazaar Office, 32, Wellington Street, Strand, W.C. — Ignoramus. Grigor's Arboriculture will probably suit you.

BOX EDGING: T. B. No. The best time is during showery weather in spring.

CAMELIAS: A. H. D. Have the bed prepared, so as to plant them out after they have done blooming, or else defer the operation till the young growth has become set.

CHRYSANTHEMUMS: T. T. The dying of the tips of the leaves is probably caused by drought at the root; unless, indeed, it may have suffered from injudicious fumigation.

CELERY: P. B. The leaves are badly attacked by a fungus—the well-known "Celery Brand," Puccinia api = Uredo api.

FRUIT TREES FOR WALLS: An Amateur. For north-west aspect try Pears and Plums, planted at, say, 10 feet apart. Sorts: Pears—Marie Louise, Louise Bonne, Glou Morceau, Doyenné du Comice, Joséphine de Malines, Bergamotte d'Espérance; Plums—Victoria, Jefferson, Transparent Gage, Belle de Septembre. For south-west aspect: Peaches—Hale's Early, Stirling Castle, Bellegarde, Walburton Admirable; Nectarines—Elruge, Lord Napier, Victoria; Apricot—Moorpark. See our Fruit Number.

FUNGI: C. Green. It is a tuft of some imperfectly developed Agaric, — probably Agaricus squarrosa. M. J. B.

MAKING LAWNS: G. R. Get the ground prepared now, or curing the dry open weather of the next month or two, and sow down with well-selected seeds next February. Rhododendrons may be removed now, or in spring. If it is only a small lawn, and you are going to lay it down with turf, do it at once.

MALFORMED ORANGES: C. H. A common occurrence. The fruit is normally made up of several segments united together; sometimes, as in your specimen, one or more get detached, or do not unite, and the result is as you see.

MRS. PINCE VINE AS A STOCK: Talpey. We have no direct experience, but incline to believe that Mrs. Pince will not prove a suitable stock to graft upon. Madresfield Court and Foster's Seedling are both excellent sorts.

NAMES OF FRUITS: George Swales. London or Five-crowned Pippin.—Mr. Croston. 1, Carlisle Codlin; 2, Ravelstone Pippin; 3, Manks' Codlin; 4, Ribston Pippin; 5, Northern Greening; 6, Gravenstein; 7, Cackle Pippin; others not recognised.—W. Hockin. Apple, Mère de Ménage. Pear, not sure of.

NAMES OF PLANTS: J. R. 1, Crataegus Crus Galli, var.; 2, C. punctata; 3, C. prunifolia; 4, C. pyrifolia, probably. The two cones sent are clearly both of one species, P. nobilis. You know best whether there is anything different in the foliage or habit to constitute one of them a variety.—R. K. Pyrus pinatifida; now considered a variety of the White Beam, P. Aria.—P. W. 1, Ceanothus azureus; 2, Retinospora juniperoides, syn. decussata; 3, Retinospora plumosa aurea; 4, Juniperus virginiana Leeania; 5, Cupressus nutkaensis.—J. Morton. Sedum spectabile, sometimes called S. Fabaria.—G. Bath. Platycodon arguta is a synonymous name for P. Sieboldii—a recently introduced Japanese shrub, with lanceolate dentate deciduous leaves, and white Philadelphus-like flowers. It is a close ally of the Deutzias.—A. Asplenium Adiantum-nigrum, [Euonymus europæus.—E. C. Hymenophyllum tubridigense.—A. McDonald. The Haller form of Asplenium fontanum.—T. Harz. 1, Adiantum concinnum; 2, Blechnum occidentale; 3, Pteris serrulata; 4, Pteris cretica; 5, Selaginella Kraussii, commonly but erroneously known as S. denticulata; 6, Lophospermum scandens.—E. G. H. Tropæolum tuberosum.

PICEA NOBILIS: T. Bury. They may be sown at once and kept in a dry, cold frame, where, if good, they will germinate next spring. Those sent to us do not, however, appear to be perfect, possibly through the female flowers not having been impregnated.

POTATOS: G. Davidson. 1. An "Amateur in Potatogrowing" is like an amateur in any other gardening pursuit—one who cultivates only for pleasure, not for profit. 2. The reply to this question—"Will a man who grows three or more acres of Potatoes for sale, plus up a stall to sell to the public, and sends out printed lists of what he has to dispose of, be allowed to compete at the Royal Horticultural Society, as an amateur or as a Potato Salesman?"—should be addressed to the Secretary of the Society; but you may learn our opinion from the reply to the former question.

RAINFALL: E. E. H. The weight of an inch of rain falling over an acre of ground is equal to 101 tons.

SCOLOPENDRIUM: F. B. The variety Cousensii is a crested and viviparous variety of the Hart's-tongue Fern, and we believe there are others that present the same characteristics.

TRAINING EPACRIS: F. T. S. Epacris should be cut down rather closely after flowering is over, and the stronger the growth afterwards obtained the better will they flower.

FOREIGN SUBSCRIBERS sending Post-office Orders are requested to make them payable at the post-office, King Street, Covent Garden, London, and at the same time to inform the Publisher at the office of this Journal.

Markets.

COVENT GARDEN, October 11.

We have been well supplied with Apples during this week, the demand being quiet, and, except for very best samples, prices easier. The first consignment of American fruit this season is just to hand. James Webber, Wholesale Apple Market.

FRUIT.

Table with 3 columns: Fruit name, Price (s. d.), and Quantity. Includes Apples, Grapes, Lemons, Melons, Nuts, Cobs, Oranges, Peaches, Pine-apples, Figs, Walnuts.

VEGETABLES.

Table with 3 columns: Vegetable name, Price (s. d.), and Quantity. Includes Artichokes, Globe, Asparagus, Beans, Cabbages, Carrots, Cauliflowers, Celery, Chilis, Cucumbers, Eodive, Garlic, Potatoes, Herbs, Horse Radish, Lettices, Mint, Mushrooms, Onions, Parsley, Peas, Radishes, Spanish, Salsify, Shallots, Spinach, Tomatoes, Turnips, Vegetable Marrows.

CUT FLOWERS.

Table with 3 columns: Flower name, Price (s. d.), and Quantity. Includes Asters, Bouvardias, Calceolaria, Chrysanthemum, Cornflower, Dahlias, Eschscholtzia, Eucharis, Gardenia, Heartsease, Heliotropes, Jasmine, Miguocette, Pelargoniums, Primula, Pyrethrum, Roses, Stephanotis, Stocks, Sweet Pea, Tropicolum, Violets.

PLANTS IN POTS.

Table with 3 columns: Plant name, Price (s. d.), and Quantity. Includes Begonias, Bouvardias, China Asters, Chrysanthemum, Clematis, Coleus, Cyclamen, Cyperus, Dracena terminalis, Euonymus, Feros, Ficus elastica, Fuchsias, Lilium, Mignonette, Myrtles, Palms, Pelargonium, Solanums, Valotta purpur.

SEEDS.

LONDON: Oct. 10.—The seed market continues to present a quiet appearance, and a general disinclination to purchase red Clover at current rates is observable.

Still lower quotations come to hand from France, but in view of the superabundant supply promised by America and other countries buyers are naturally loath to operate. The latest reports from Germany are more promising than the early ones. To-day's advices from the United States confirm previous information as to the largeness and goodness of the Clover crop; their home consumption this season will, it is said, be heavy. In consequence of the high prices of last season, Western farmers put in much less Clover than usual, but this year the seedings will be above the average; the cheapness and fineness of the seed will also stimulate the domestic demand. As to the probable range of prices obtainable for the large surplus which will be left after the Americans have supplied their own wants, this will naturally be regulated by the export demand from Europe; consequently if merchants on this side of the Atlantic adopt a waiting policy, and hold off from buying, they will probably be enabled later on to lay in their stock at a reasonable figure. In Alsike and Trefoil there is just now very little business doing, but for White Clover more inquiry has prevailed. Foreign Italian is offering at low rates. Some new American Timothy has just arrived on this market. For Canary seed the sale keeps extremely slow; new home-grown samples are now to hand. Fine new white Millet can now be bought on Mark Lane at a moderate price. White Mustard shows on the past few weeks a heavy drop, and the downward tendency meets with no arrest. Rape seed is also rather weaker. For Blue Peas there is a brisk request at the late advance. Owing to the long-continued lack of rain the winter Tare trade has latterly been very dull. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E. C.

CORN.

At Mark Lane on Monday the demand for English Wheat was very slow, but owing to the recovery which had taken place at New York holders were firm, and, in some instances, an advance of 1s. per quarter took place. In foreign Wheat choice descriptions were held for more money. Barley sold slowly at the recent decline. Malt was quiet at about late rates. For Indian corn the prices were supported. The Oat trade was steady, without material change in prices. For Beans and Peas the quotations ruled firm. Flour was in moderate demand at late rates. Wednesday's market was quiet, with little or no change in the quotations. Fine dry samples, whether of Wheat, Barley, or other description of produce, were scarce, and fully as dear as on Monday.—Average prices of corn for the week ending October 6:—Wheat, 55s. 11d.; Barley, 44s. 2d.; Oats, 24s. 5d. For the corresponding period last year:—Wheat, 46s. 3d.; Barley, 40s. 2d.; Oats, 25s. 5d.

CATTLE.

At Copenhagen Fields on Monday the choicest quality beasts were rather dearer; for other kinds trade was slow, owing to large supplies at the dead market. The number of sheep was smaller than last week, but quite equal, however, to the demand. Some choicest half-breeds made 7s., but our quotations were the more general. Trade was very dull for calves. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 6d. to 6s.; calves, 4s. 6d. to 5s. 6d.; sheep, 5s. 4d. to 5s. 8d., and 6s. 4d. to 6s. 10d.; pigs, 4s. to 4s. 10d.—On Thursday the supplies of beasts were short, but more than equal to the demand, which ruled heavy. Prices must be quoted lower than on Monday. As regards sheep the supplies were very short, and well-breds were tolerably steady, but other kinds were irregular in value. Calves sold at about late rates.

HAY.

At the Whitechapel market on Tuesday trade was quiet, and prices unchanged. There was a large supply.—Prime old clover was quoted at 100s. to 102s.; inferior, 85s. to 95s.; good new, 100s. to 105s.; prime meadow hay, 90s. to 115s.; inferior, 70s. to 85s.; and straw, 44s. to 55s. per load.—On Thursday there was a fair supply of hay and straw on sale. There was a brisk trade for good Clover at from 100s. to 105s., but prices were lower for hay.—Cumberland Market quotations:—Superior meadow hay, 110s. to 120s.; inferior, 84s. to 98s.; superior Clover, 134s. to 140s.; inferior, 95s. to 126s.; and straw, 54s. to 60s. per load.

POTATOS.

The Borough and Spitalfields markets reports state that the arrivals of Potatoes at these markets have been moderate, but sound qualities are scarce, and command high prices. For inferior produce the trade is slow at somewhat irregular quotations. Kent Regents, 220s. to 240s. per ton; Essex ditto, 200s. to 230s.; rocks, 90s. to 100s.; kidneys, 110s. to 130s.; Victorias, 120s. to 140s.; American Rose roots, to 120s.—The imports into London last week consisted of 38,125 bags from Hamburg, 2222 sacks Rouen, 2725 Dunkirk, 9316 bags Bremen, 1179 Antwerp, 1578 Haringen, 3838 Ghent, 1477 Boulogne, 775 Rotterdam, and 255 barrels New York.

COALS.

On Monday there was a good market demand for house coals at the prices quoted last week. Wednesday's market was characterised by a brisk business, and quotations for house coals were advanced 6d. per ton. Quotations:—Bower's West Hartley, 17s. 3d.; Walls End—Hetton, 22s.; Hetton Lyons, 19s. 6d.; Lambton, 21s. 6d.; Original Hartlepool, 22s.; Newbottle, 18s. 6d.; South Hetton, 22s.; East Hartlepool, 21s. 9d.; South Hartlepool, 20s.; Tees, 21s. 9d.

AVENUE TREES.

PLANE TREES.—Several thousands of the true Platanus occidentalis, from 10 to 20 feet high, straight stemmed, stout, and splendidly rooted. LINES, 10 to 20 feet high. POPLAR, canadensis, 12 to 20 feet high. These trees have been grown expressly for Street and Avenue Planting. They are to be seen growing at Knap Hill, and are, without question, the finest stock of their kinds to be found in any Nursery in Europe. ANTHONY WATERER, Knap Hill, Woking, Surrey.

CHOICE WINTER FLOWERS.

RHODODENDRON MULTIFLORUM, 2s. 6d. to 3s. 6d. each. PRÆCOX, 1s. 6d. to 2s. 6d. each. AZALEA DAVIESII, 2s. 6d. to 3s. 6d. each. HYBRIDA ODORATA, 2s. 6d. to 3s. 6d. each. All the above are beautiful bushes, well filled with bloo buds. Descriptive List of these and other Novelties forwarded on application to ISAAC DAVIES, Nurseryman, Ormskirk.

Surplus Stock. INDIAN AZALEAS, from 3000 to 4000 nice flowering plants of the best varieties, 15s. to 24s. per dozen. Descriptive List forwarded on application. DAPHNE INDICA RUBRA, from 1000 to 2000 plants, 8s. to 30s. per dozen. LILIUM AURATUM, home-grown Bulbs, that have borne from four to eight flowers each this season, 12s. to 18s. per dozen. ISAAC DAVIES, Nurseryman, Ormskirk.

Advertisement for 'Beautiful Flowers in Winter & Spring' by Carter's. Includes a table of prices for various flower collections like Hyacinths, Tulips, Crocus, and a list of plants for conservatory and open ground.

THE QUEEN'S SEEDSMEN, HIGH HOLBORN, LONDON, W.C.

SPECIMEN CAMELLIAS, from 1 to 30 Guineas each. [and upwards.]

"Hyacinths were again the main feature—Mr. WM. PAUL taking first prize with a collection that were as near absolute perfection as in the present state of our knowledge we can imagine."—*Gardeners' Chronicle*.

"Hyacinths formed the most important feature of the show, the principal exhibitor being Mr. WM. PAUL, of Waltham Cross, who was far in advance of any other in the size and beauty of the noble spikes which he placed in competition."—*Journal of Horticulture*.

"It is due to Mr. WM. PAUL's wonderful group of 24 Hyacinths, to which was awarded the First Prize, that a tribute should be borne here to their incomparable quality."—*The Florist*.

PAUL'S NURSERIES and SEED WAREHOUSE,
WALTHAM CROSS, HERTS.

PICEA CONCOLOR VIOLACEA.

Of this beautiful and distinct Rocky Mountain SILVER FIR we are glad to be able to offer established Plants, received by us, direct from its native habitat, two years ago. Whilst possessing some resemblance to P. LASIOCARPA our plant is thoroughly distinct, the leaves being rounder or needle-like in form, and verticillate rather than pectinate. The colour also is of a uniform silvery glaucous hue, both above and beneath, and is very aptly described by the name it bears. To all cultivators of the choicer Conifers, or Planters for Landscape effect, this must prove a valuable introduction.

- Plants in Pots, 3 to 5 inches high 10s. 6d. each.
- Plants in Pots, 5 to 7 inches high 15s. 0d. "
- Plants in Pots, 7 to 10 inches high, bushy .. 21s. 0d. "

JAMES BACKHOUSE & SON, THE NURSERIES, YORK.

Our Collection of CONIFERÆ and other ORNAMENTAL TREES is extensive and fine, the Plants as a rule being well-grown and well-rooted.

CURRANTS, 3-yr. to 5-yr., 60s. to 75s. per 1000.

T. EVES, Gravesend Nurseries. Established 1810.

BEDDING VIOLAS and PANSIES.—

The best of all plants for Spring, Summer, and Autumn Bedding. They require no special treatment, are perfectly hardy, and continue in flower from early spring till long after all other bedding plants have been removed. They are now so generally known and appreciated that it is unnecessary to do more than remind Planters that this is the best time to secure a stock. The Subscribers have an immense quantity of healthy, well-rooted plants of all the best varieties, that have been thoroughly tested, and in order to place them within the reach of all they make the following special autumn quotation (selection being left to themselves), post-free to any part of the kingdom—

- 100, in 10 sorts, 16s. 6d. to 21s.
- 50, in 10 sorts, 10s. 6d. to 12s. 6d.
- 25, in 5 sorts, 6s. 6d.

Descriptive CATALOGUES and special Prices will be sent on application to the Trade or to those requiring large quantities or particular varieties.

AMIES' CHEMICAL MANURE.

USED BY THE ROYAL HORTICULTURAL AND BOTANIC SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.

PREPARED IN A FINE, DRY, INODOUROUS POWDER.

Price, £12 per Ton; 15s. per Cwt.; and in Canisters, 1s., 2s. and 4s. each.

Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to

AMIES' CHEMICAL MANURE CO. (LIMITED),
79, MARK LANE, LONDON, E.C.

JOHN SCOTT, The Royal Seed Stores, Yeovil.

GISHURST COMPOUND.—Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrrips, Greenfly, and other Blight, in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s., 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited).

RUSSIA MATS.—A large stock of Archangel and Petersburg, for Covering and Packing (price on application for Archangel)—Petersburg, 60s. to 100s. per 100; superior close-weave, 40s., 50s. and 55s. per 100; Packing Mats at 20s., 30s., and 35s. per 100; and all other descriptions of Mats at equally low rates, at

OF

Messrs. ANDREW McLAREN & CO., LONDON,

(Who have relinquished this branch of their business),

WILL FOR A FEW WEEKS OFFER THESE GOODS AT

REDUCED PRICES.

HOT-WATER APPARATUS ERECTED COMPLETE, OR THE MATERIALS SUPPLIED AT WHOLESALE PRICES.

RUSSIA MATS, for Covering Garden Frames.—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post-free on application.
JAS. T. ANDERSON, 149, Commercial Street, Shoreditch, London, E.C.

Wholesale Russia Mat Merchants.
NEW ARCHANGEL MATS,
ST. PETERSBURG MATS, of all qualities and sizes. RAFFIA FIBRE, &c. Firms are requested to send cash or reference in first transactions.
MARENDAZ AND FISHER, James Street, Covent Garden.

RUSSIA MATS for Covering from Frost,
from 30s. to 70s. per 100; good for packing from 20s. GUNNY BAGS, from 3½d. each. Delivered free to any station in London.
SUTHERLAND, SON AND CO., 11, Fenchurch Buildings, Fenchurch Street, London, E.C.

Rosher's Garden Edging Tiles.
THE ABOVE and many other PATTERNS are made in materials of great durability. The plainest sorts are specially suited for KITCHEN GARDENS, as they harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do "grown" Edgings, consequently being much cheaper.
GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design.
F. ROSHER AND CO., Manufacturers, Upper Ground Street, Blackfriars, S.E.; King's Road, Chelsea, S.W.; Kingsland Road, E.
Agents for LOOKER'S PATENT "ACME FRAMES," PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT BEADED GARDEN WALL BRICKS.
Illustrated Price Lists free by Post. The Trade supplied.

ORNAMENTAL PAVING TILES,
for Conservatories, Halls, Corridors, Balconies, &c., from 3s. per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection.
WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Grooved and other Stable Paving of great durability. Wall Copings, Drain Pipes and Tiles of all kinds. Roofing Tiles in great variety. Slates, Cement, &c.
F. ROSHER AND CO., Brick and Tile Merchants.
See addresses above.

SILVER SAND,
fine or coarse grain, as desired. Prices by Post per Ton or Truck-load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of sand free by post.
FLINTS and BRICK BURRS for Rockeries or Ferneries.
KENT PEATS or LOAM supplied at lowest rates in any quantities.
F. ROSHER AND CO.—Addresses see above.
N.B.—Orders promptly executed by Rail or to Wharves. A liberal Discount to the Trade.

HORTICULTURAL WINDOW GLASS,

THOMAS GREEN AND SON, Smithfield Ironworks, Leeds; and 54 and 55, Blackfriars Road, London, S.E.
Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone.
This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.
Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.
UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.
"The Ryleys, Alderly Edge, Manchester.—Messrs. Hill & Smith.—Sir,—For some 20 years I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted.
—Yours respectfully, ALFRED LOWE, J.P."
Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 118, Queen Victoria Street, London, E.C., from whom only it can be obtained.

HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which one is genuine.

We can supply Foundation Plates—which form Ash-pit—and Smokestacks, if wanted, thereby doing away with the necessity for even a single brick in their erection.

	A	B	C	D	E
Foundation Plate ..	5 s. d.	5 s. d.	5 s. d.	5 s. d.	5 s. d.
Smokestack, Damper, and Soot-Door ..	35 0	45 0	60 0	75 0	90 0
Furnace and Ash-Pit, Frame and Doors; also Furnace Bars, Bearers, Dumb-Plate, &c. ..	30 0	40 0	50 0	60 0	70 0

Foundation Plates are arranged to heat the air before it is sent into the ash-pit at back, and furnace-doors to heat the air before its admission into the furnace; furnishing in fact two "hot air" blasts to the furnace; the admission of large volumes of cold air being most injurious to the economical working of the furnace.

In preparation an entirely NEW SERIES of SEVENTY BOILERS, embracing a large variety suitable for small places, &c., and all specially adapted for low situations where shallow boilers are a necessity. Particulars on application.

No Labor Required.

HAYWARD TYLER & Co.,
84, WHITECHURCH STREET, LONDON.

THE NEW PUMPING ENGINE

For Sale, a
STEVENS' IMPROVED TRENTHAM
WROUGHT IRON HORTICULTURAL BOILER,
6 feet long by 3 feet diameter, fitted with Inlet and two Outlet
Pipes, Fire-door and Grate complete. For price and particu-
lars apply to
HILL AND SMITH, Brierley Hill Ironworks, Dudley.

CRITCHLEY'S PATENT
HEAT REGULATOR,
AN APPARATUS FOR REGULATING THE HEAT
IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe or Supply of Water from Boiler. C, D, Pipes for Circulating Hot Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Retaining Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.
The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.

The following Testimonial has been received:—
"Berkeley Castle, April 13, 1875.
Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot-Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it the greatest improvement that has come out for horticultural purposes.
"I am, Gentlemen, yours truly,
"R. H. CROOK,
Gardener to the Right Hon. Lord Fitzhardinge."
Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

GROSVENOR WORKS, CHELTENHAM.

JOSEPH BRAMHAM, HORTICULTURAL
and **HOT-WATER ENGINEER, WIRE WORKER, WEAVER,**
&c., 104, Dale Street, and 44, Elizabeth Street, Liverpool.
J. B. strongly recommends the **ALBERTON PRIORY BOILER** as one of the most powerful for extensive work. He has fixed one capable of heating 10,000 feet of 4-inch piping. See *Gardeners' Chronicle*, p. 647. Also his **WELDED WROUGHT IRON WATERWAY BACK** for ordinary Saddle Boilers. These Backs can be fixed to any Boiler now in use, and are a great saving in fuel and labour. He is also prepared to fix any kind of Boiler made.
Manufacturer of the Registered **LIVER FRONT** for large Boilers, **IRON and WIRE WORK** in all branches. References from Noblemen and Gentlemen for work done.
Plans and Estimates given.

STEVENS' TRENTHAM GREENHOUSE BOILER,
After long experience, has proved the most **SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER** extant; recently improved.

Copy of a Testimonial.
"Royal Exotic Nursery, King's Road, Chelsea, S.W.—Aug. 8, 1877.
Messrs. SILVESTER.—In reply to your enquiry as to our opinion of your Stevens' Trentham Boilers, we do not hesitate to pronounce them to be by far the best Boilers we have ever used. Our establishment is a very large one, and we have tested most of the various descriptions of Boilers which have been brought out from time to time. We originally commenced with one Trentham Boiler, and we have now *thirteen* of various sizes at work. For certainty of action, economy in fuel, and freedom from breakdown, we have never had a Boiler at all equal to the Stevens' Riveted Trentham Boilers supplied by you, and we have never felt so little anxiety in connection with our hot-houses during the cold winter months as we do now.
"We are not in the habit of giving testimonials, but we think this may fairly be an exception to our rule, as the matter is one of such importance to the Gardening Public generally, and our experience has led us to form a very decided opinion.
"We are, Gentlemen, yours faithfully,
"JAMES VEITCH AND SONS."
For Illustrations, with full particulars, apply to the Sole Makers,
F. & J. SILVESTER,
HOT-WATER ENGINEERS, &c., &c.,
Castle Hill Works, Newcastle, Staffordshire.
Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

THE ORCHARDIST.

ALL FRUIT GROWERS SHOULD OBTAIN A COPY BEFORE
ORDERING THEIR TREES.

Apply to J. SCOTT, The Royal Nurseries, Merriott, Somerset,

Whose Collection is the finest in the Kingdom—2000 sorts of PEAR, 1500 sorts of
APPLE, 150 sorts of PLUM, with other kinds in proportion, being grown. The great bulk
of these are described in the "ORCHARDIST," the best work on Fruit Trees in the English
language.

The Advertiser has numbers of Letters from Britain, America, Australia, France, Belgium, &c.,
all eulogising the work as the best the writers have seen.

The Trees are this season in fine health. Price Lists forwarded.

Copies to be had at

37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.

 Post-office Orders to be made payable to M. E. PVNAERT, at the Chief Post-office, Ghent.

ADVERTISERS are requested to note that although we do not object to receive Letters to be called for, we cannot undertake to forward them.

PARTNER WANTED, with about £400, to join Advertiser in a fast growing locality. Lease eighty years. Ten-roomed House; 1½ acre Grounds; Eighteen large Greenhouses; Pits and Frames, heated. First-class Stock.—A. B. W. Evans, Royal Nursery, Penge, S.E.

MESSRS. JAMES VEITCH AND SONS require a first-class GARDENER, to proceed at once to America (U.S.A.); he must have a thorough knowledge of Orchids, choice Stove and Greenhouse Plants, as well as being a good Cultivator of Fruit and Vegetables. Wages, £120 per annum, house, &c.—Address, with full particulars, to The Royal Exotic Nurseries, Chelsea, S.W.

WANTED, as SECOND GARDENER, a married Man, without children; strong, active, and with a fair knowledge of Stove and Greenhouse Plants. Wages, £1 per week, with good cottage and milk. None need apply without a first-class character.—Mr. CULLIFORD, Gardener, Round Hill House, Sydenham, S.E.

WANTED, a SECOND GARDENER—married, age about 30; one who understands his business. A Christian will be preferred.—Apply, by letter, to J. M., Messrs. Knight & Fletcher, 37, Cheapside, stating full particulars, with length of time in last situation.

WANTED, as UNDER GARDENER, a Man who understands the Management of Cows, Pigs, and Poultry. Good character required.—Address, stating age, W., Wilson's, Newspaper Agent, Fulham, S.W.

WANTED, a FOREMAN, for a Market Garden of 12 acres; one accustomed to Pruning Trees and General Cultivation.—Apply, stating terms and qualifications, to Mr. BOWLEV, Surveyor, 28, Abingdon Street, Westminster, S.W.

WANTED, IMMEDIATELY, an OUTDOOR NURSERY FOREMAN. Liberal wages to a competent Man.—R. THORNHILL, Nurseries, Bowdon, Cheshire.

WANTED, a respectable young Man, as PROPAGATOR of Stove and Greenhouse Plants. One from a Market Nursery preferred. None need apply whose character and abilities will not bear strictest investigation.—B. A., *Gardeners' Chronicle* Office, W.C.

POUNCE AND SONS require, for their Nursery at Hendon, a PROPAGATOR and GROWER of Hardwooded and Stove Plants, and experienced OUTDOOR NURSERY HANDS.—Forward particulars and terms to 15, Westbourne Grove, W.

WANTED, a COWMAN and UNDER GARDENER; must have a good character and thoroughly understand Cows.—Address, stating full particulars, L. H., Mr. Howard's Printing Office, Sydenham, S.E.

WANTED, Active Young MEN, about 20 years of age, in the Jobbing Department, at ROBERT GREEN'S Floral Establishment, 28, Crawford Street, Bryanston Square, W. Must understand Mowing, Creeper Training, &c.—Apply any morning before 10 o'Clock.

Seed and Flower Trade.

WANTED, an ASSISTANT, from 18 to 22 years of age, with a knowledge of Retail Business, Seeds, Plants, and Sundries.—State age, experience, and under whom you have served, wages expected, and other particulars, and address by letter only to A. HENDERSON, Sion Nursery, Thornton Heath, Surrey.

WANT PLACES.

E. G. HENDERSON

AND SON have many excellent GARDENERS with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

E. P. DIXON can at present recommend several excellent GARDENERS, and will be pleased to answer any enquiries from Ladies and Gentlemen requiring such.—The Yorkshire Seed Establishment, Hull.

GARDENER (HEAD).—Practical. Good reference.—ROBERT SLEIGHTHOLM, Farfield, Arnlcy, Leeds.

GARDENER (HEAD).—Age 34, married; thoroughly experienced in all branches of the profession. Five years in last situation. Excellent testimonials.—Mr. R., 9, Mitchell Street, Weymouth.

KINAHAN'S LL WHISKY.

Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.
 DINNEFORD AND CO.,
 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S PILLS.

Nothing preserves the health so well as an occasional alterative in changes of weather, or when the nerves are unstrung. These Pills act admirably on the Stomach, Liver, and Kidneys, and so thoroughly Purify the Blood that they are the most efficient remedy in warding off derangements of the Stomach, Fever, Diarrhoea, Dysentery, and other Maladies, and giving tone and energy to Debilitated Constitutions. All who have the natural and laudable desire of maintaining their own and their family's health, cannot do better than trust to Holloway's Pills, which cool, regulate, and strengthen. These purifying Pills are suitable for all ages, seasons, climates, and constitutions, when all other means fail, and are the female's best friend.

DR. LOCOCK'S PULMONIC WAFERS.

(—this week)—Mr. STEAD, *Chemist, High Street, Lees, Manchester*, writes:—"I am certain that if your Wafers were more known, they would confer greater benefits. I have customers who speak very highly of them." Dr. Locock's Wafers instantly relieve and rapidly cure Asthma, Consumption, Bronchitis, Coughs, Colds, Shortness of Breath, and taste pleasantly. Sold at 1s. 1/2d. and 2s. 6d. per box.

SPECIAL ADVANTAGES OF RENDLE'S PATENT SYSTEM OF GLAZING.

This system is now being universally adopted by Her Majesty's Government, several of the principal Corporations, including the Metropolitan Board of Works, Commissioners of Sewers, and the New Winter Garden Companies throughout the Country.

There is an enormous Saving in the Maintenance and Repairs of Roofs on this System—say from 80 to 90 per cent.—and there is no reason why a Roof should not be as perfect in 20 years as the first week, because all the perishable materials, such as wood, iron, or paint, are completely covered by the glass from the destructible influences of the weather.

Another great recommendation is, that there is no breakage from contraction or expansion either from heat or cold, as the glass has full play in every direction. Tens of thousands of squares are broken from this cause every year. Nor is there any breakage from vibration of large Railway Roofs in heavy gales of wind, or from the passing of express or fast trains. Indeed, it is well known that a puttied roof is never perfect in a station where express trains run through.

In adopting this System, all the everlasting expenses of re-painting or re-puttying are completely done away with; and as it is now used by several of the Great Railway Companies, an enormous saving will be effected—it will have considerable influence in supplying an addition to the yearly dividends.

SUMMARY OF SPECIAL ADVANTAGES.

- 1.—Saving of from 80 to 90 per cent. in maintenance and repairs.
- 2.—No breakage from contraction or expansion, from heat or frost.
- 3.—No breakage from vibration caused by heavy winds or passing trains.
- 4.—Squares of glass can be instantly replaced.
- 5.—The construction is very strong and durable.
- 6.—The glass can be put on in one-fourth the time of the old plan.
- 7.—No drip from condensation.
- 8.—Putty, cement, felt, &c., are entirely dispensed with.

To Florists.

TO BE SOLD, a genuine old-established **BUSINESS** (in the same hands ten years)— $\frac{1}{2}$ acre of ground, two houses, Potting Shed, Sets of Frames, &c. Stock optional. Premium £225. Lease five years. Rent £10 per annum. Particulars of **RUBBER, FULLER and MOON**, Estate Agents, Croydon and Reigate. (3059)

To Nurserymen and Others.

TO BE DISPOSED OF, one of the oldest established **NURSERY BUSINESSES** in the North of England, with valuable connection.

The executors of the late Mr. John Harrison, of the North of England Nurseries, Catterick Bridge and Scorton, are open to treat with a gentleman possessing capital, for the disposal of the business, which has an established connection of nearly 50 years.

The Nurseries consist of about 60 acres of Freehold Land, about 40 acres of which are stocked with a choice Collection of Roses and General Nursery Stock. There are good Residences in the Grounds, and fine Ranges of Glass, close to the Catterick Bridge Station of the North-Eastern Railway, situate between Darlington and Richmond, and offering unusual facilities for doing a large and profitable business. A large portion of the purchase money could remain on security of the property at a reasonable rate of interest. Possession could be given at any time as a going concern. Principals or their Solicitors only may apply to the undersigned,

A. E. HARRISON, Solicitor, Church Yard, Rotherham.

TO BE DISPOSED OF, a Small **FLORIST'S BUSINESS**, with Two substantially built Houses, heated with hot water and well stocked with Spring Bedding Plants, 150 feet of Frames, with light, 6 feet; Three Green's Mowing Machines, Ladders, Barrows, Tools, &c., Eight-roomed House on lease.

G. C., 35, Grove Lane, Camberwell, Surrey.

TO BE DISPOSED OF, **TWO ACRES OF LAND**, planted with choice Fruit Trees, in full bearing; also covered with Nursery Stock in fine condition. It is under a Nobleman, in the county of Nottingham, within a small distance of three Markets. A good opening for a working man with a little capital. The Valuation about £750. More Land could be obtained if required at reasonable rent. For particulars, G. F., Gardeners' Chronicle Office, W.C.

White Cross Nurseries, Hereford.

IMPORTANT to NURSERYMEN, SEEDSMEN, FLORISTS, and Others.
TO BE SOLD, by Private Treaty, as a going concern, in consequence of a Dissolution of Partnership, the whole of the valuable **STOCK-IN-TRADE**, with 8 Greenhouses, Propagating Houses, 2 Vineries, and 4 Ranges, about 500 feet in length, of Pits, fully stocked, and in good repair; Horse, Van, Spring and Heavy Carts, Tools, Implements, Utensils, and Plant, upon and belonging to the White Cross Nurseries, situated on the confines of the City of Hereford, together with the Stock of Agricultural and Garden Seeds, Plants and Effects at the Seed Warehouse, occupied in connection with the Nurseries, and situated in Library Buildings, Hereford, aforesaid.

The Nurseries (with the Cottages and Buildings thereon) cover an area of about 23 acres, are well stocked with the choicest variety of every kind of Fruit, Standard and Dwarf Roses, and other Trees, Ornamental and other Shrubs, Plants, &c., are well and pleasantly situated, close to the City of Hereford, and within a few minutes' walk of the Barton Railway Station.

The Nurseries, together with about 12 acres of Pasture Land, are held under a Lease, of which about 4 years are unexpired, and will be included in the purchase.

To view, apply to Mr. CHARLES WHITING, the Foreman at the Nurseries. Any further particulars which may be required may be obtained on application to H. C. BEDDOE, Esq., Hereford, 1, 05, Messrs. DEWES, SON and WILKS, of Coventry, Joint Solicitors.

Sealed Tenders (marked "Tender for White Cross Nurseries") to be forwarded to Mr. HENRY MERRICK, of Earl Street, Coventry, Public Accountant, not later than October 25 next. The Tenders do not bind themselves to accept the highest or any Tender.

To Nurserymen and Gardeners.

TO BE SOLD or LET, an old-established **NURSERY, SEED, and FRUIT GROWING ESTABLISHMENT**, in an important and fashionable town, in one of the midland counties. An excellent opportunity for an experienced Gardener with moderate capital. For particulars apply to ALEX. MCKENZIE, 1 & 2, Great Winchester Street Buildings, London, E.C.

To Nurserymen, Florists, and Others.

TO BE LET, with Immediate Possession, **CRESCENT ROAD GRAPERIES**, Worthing, standing on an acre and a quarter of ground. Nearly 500 feet run of Glass; good Cottage. No Valuation on entering. For particulars, or for view, apply to **GARDENER, The Graperies, Crescent Road, Worthing.**

THE IMPROVEMENT OF LANDED ESTATES, By **DRAINAGE, ENCLOSING, CLEARING**, The **ERECTION OF FARM BUILDINGS and COTTAGES**, **WATER SUPPLY, &c.**

The Land Loan and Emfranchisement Co. (Incorporated by Special Act of Parliament)

ADVANCES MONEY:

1st.—To the **OWNERS of SETTLED and OTHER ESTATES**, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing, and General Improvement of Landed Property in any part of the United Kingdom.

2d.—To the **OWNERS of SETTLED ESTATES** in ENGLAND, for the Erection or Completion of Mansions, Stables, and Outbuildings, and for the Construction or Erection of Reservoirs, and other Works of a permanent nature, to supply Water for the use of the Estate, or for any other purpose.

3d.—To **LANDOWNERS** generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.

4th.—To **INCUMBENTS**, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.

5th.—To **COPYPHOLDERS**, for the Emfranchisement of Copyhold Lands.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years.

No Investigation of the Landowner's Title is necessary.

Forms of application, and all further particulars may be obtained of Messrs.

RAWLANCE and SQUAREY, 22, Great George Street, Westminster, S.W., and Salisbury of Messrs. ASHURST, MORRIS, CRISP, and CO., 6, Old Jewry, London, E.C.; of Messrs. Winter and Spring Flowering Plants.

MESSRS. JOHN STANDISH AND CO.'S stock of these is unusually fine this season, and includes the following:— AZALEA INDICA, bushy and well budded, in good variety. BOUVARDIAS, good bushy plants. CAMELLIAS, good plants and well budded. CARNATIONS, Miss Jolliffe and others. EPACRIS, good plants. ERICAS, Hymenalis, Sindyriana, Wilmoreana, ventricosa varieties, and others. ROSES, Tea-scented and H.P.'s, in great variety. POINSETTIA PULCHERRIMA. SOLANUM, well-berried plants, and other plants. They have also a great variety of PALMS and other plants suitable for decoration; also of ADIANTUM and many other FERNS, besides a varied stock of STOVE and GREENHOUSE PLANTS and GRAPE VINES. CATALOGUES post-free on application. Royal Nurseries, Ascot, Berks.

Alnwick Seedling Grape Vine.

D. P. BELL begs to offer young plants of the above Vine, the true variety as grown at Clive House, from which the only exhibit has been made, and for which he received the First-Class Certificate from the Fruit Committee of the Royal Horticultural Society, December 6, 1876, regarding which the report of the Committee, as given by the Journal of Horticulture, is as follows:—"The bunch is large and heavily shouldered, with a stout stalk. The berry stalks are stout, and the berries large and roundish oval, frequently with a suture furrow; skin quite black and membranous, covered with a fine bloom; flesh firm, tender, very juicy, and sweet. It was unanimously awarded a First-Class Certificate. This is a far superior fruit to Alicante, and will no doubt prove to be a late-keeping variety of great value." It is important that the public should know that this, the only certificated variety (and therefore the original), has been exclusively raised at Clive House, and cannot be had elsewhere. Price 15s. each. The fruit now hanging on the parent Vine may be seen on application.

New Exhibition and Decorative Fuchsias.

JAMES LYE, Clyffe Hall, Market Lavington, Wilts, has the pleasure to offer the following fine new varieties of his own raising, unrivalled for their high-class qualities, excellent habits, and free-flowering properties:—

DARK VARIETIES.

Charming. James Lye. Gem of the West. Royal Standard. Mr. James Huntley. Elegance.

LIGHT VARIETIES.

Beauty of Wilts. Mrs. Huntley. Letty Lye. Delicata. Blushing Bride. Miss Lye.

The above fine varieties have been most favourably reported on in the Gardeners' Chronicle for June 9, and the Gardeners' Magazine for June 23. A coloured illustration of Mr. James Huntley, Letty Lye, Mrs. Huntley, and Royal Standard, appeared in the Floral Magazine for October. A Descriptive List can be had on application. Plants are now ready, and Orders will be executed as received. Price the set of twelve varieties, £1 10s.; per plant, 3s. Post-office Orders payable to JAMES LYE, Market Lavington Office.

MR. A. VAN GEERT, NURSERYMAN, Ghent, Belgium, begs to offer fine Plants of Budded CAMELLIAS, Indian AZALEAS, Ghent AZALEAS, LATANIAS, CHAMÆROPS, PHENIX and other PALMS, table sizes, also SPIRÆA JAPONICA, fine clumps. Prices on application. The New CATALOGUE, just issued, sent to applicants.

Rhododendrons.

ISAAC MATTHEWS AND SON have to offer the following RHODODENDRONS—100,000 fine bushy plants, thinly grown and well rooted, nice round plants:— RHODODENDRON SPLENDIDUM, white, 1 to 1 1/2 foot, 37s. 6d. per 100; 1 1/2 to 2 feet, 50s. per 100; 2 to 2 1/2 feet, 60s. per 100. CALGASTUM PICTUM, scarlet, 1 to 1 1/2 foot, 50s. per 100; 1 1/2 to 2 feet, 60s. per 100. JACKSONII, scarlet, 1 foot, 50s. per 100; 1 to 1 1/2 foot, 60s. per 100; 1 1/2 to 2 feet, 75s. per 100. WOOLLERII, scarlet, 1 to 1 1/2 foot, 60s. per 100; 1 1/2 to 2 feet, £5 per 100. HYBRIDS, from all choicest named varieties, 1 foot, 20s. per 100; 1 to 1 1/2 foot, 30s. per 100; 1 1/2 to 2 feet, 40s. per 100. PONTICUM, 9 to 12 inches, 50s. per 100; 12 to 15 inches, 10s. per 100; 15 to 18 inches, 15s. per 100; 18 to 21 inches, 40s. per 100; 2 to 3 feet, 50s. per 100. YEW, English, 6 to 9 inches, 40s. per 100; 9 to 12 inches, 50s. per 100; 12 to 15 inches, 70s. per 100. English, bushy, 15 to 18 inches, 20s. per 100; 1 1/2 to 2 feet, 30s. per 100; 2 to 2 1/2 feet, 40s. per 100. English, very bushy, 2 1/2 to 3 feet, 60s. per 100. CURRANTS, Black, very strong, 10s. per 100. GOOSEBERRIES, strong, 10s. to 12s. 6d. per 100. CATALOGUES can be had on application to The Nurseries, Milton, Stoke-on-Trent.

VIOLETS, SWEET VIOLETS.

MARIE LOUISE, double, light blue, white centre, flowers very free and continuous from September to May. VICTORIA REGINA, large single Violet, very fine. WHITE CZAR, the best white. BLANDYANUM, large double Violet. KING OF VIOLETS, large double Violet. REINE DES VIOLETS, large double white. NEAPOLITAN, double lavender. Single lavender. Strong clump of the above 6s. per dozen, 40s. per 100, suitable for potting in 48-inch pots, or forming beds and masses in flower gardens. Now is the time to plant to ensure flowers all winter and spring. BELLE DE CHATENAV, new double white, 1s. 6d. each. PATRIE, new double blue, very free flowering, 1s. each. One small plant of the ten varieties free by post 5s. 6d. Trade price on application. FREDERICK PERKINS, Nurseryman, Regent Street, Leamington.

Vines and Strawberries.

"Plant now to ensure a full crop of fruit next season." FRANCIS R. KINGHORN begs to announce that his stock of VINES, including all the leading varieties, is very extensive, and in excellent condition this season. The Canes are very fine, well ripened, and perfectly free from disease. Strong Planting Cans, 3s. 6d. to 5s. each; strong Fruiting ditto, 7s. 6d. to 10s. 6d. each. Also his collection of STRAWBERRIES includes all the most popular kinds, and are ready for immediate planting. Prices in pots, 15s. to 20s. per 100; from the open ground, 3s. to 5s. per 100. Less numbers than 100 of any variety can be had, if desired. Prices to the Trade and LISTS post-free, on application. Sheen Nursery, Richmond, Surrey.

Vines—Vines—Vines.

B. S. WILLIAMS begs to announce that his VINES this year are in unusually fine condition, and are now ready for distribution. NEW LATE-KEEPING BLACK GRAPE, "ALNWICK SEEDLING."—This Grape was exhibited before the Fruit Committee, South Kensington, February 6, 1876, under the name of Clive House seedling, a name the Committee have since thought fit to alter. The following is the description given by the Fruit Committee:—"It is a seedling between the Black Morocco and an unnamed variety raised at Wortley. The bunch shown was of fair size and well shouldered, and the berries large, oval in form, and jet black in colour, with a thick skin. The flavour was decidedly good, partaking of the rich sparkling flavour of the Black Morocco, but much sweeter. It has been raised in February, and will, no doubt, keep longer and prove a better Grape for general cultivation than the Black Alicante." This has been awarded a First-Class Certificate. The stock offered is from the original plant. Early orders are respectfully solicited, as the stock is limited. Price 21s. and 42s. each. For Detailed List see BULB CATALOGUE.

NEW FIG, "HARDY PROLIFIC."—The fruit of this hardy Fig is about the medium size, Pear-shaped, rather tapering towards the stalk. The flesh is very sweet and luscious. It was introduced from France some few years ago, and has proved itself perfectly hardy. It must become a general favourite, as it is a very abundant bearer, either in pots or in a cold house, as well as on an open wall. It also ripens earlier than any other variety we know of. Price 10s. 6d. each. Extra sized fruiting plants, 21s. each. B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London, N.

To the Trade.

MESSRS. LEVAVASSEUR AND SON, NURSERYMEN, Ussy, Calvados, France, have an immense stock of Seedling FOREST TREES, Hardy Conifers, and other SHRUBS, for transplanting and transplanting several millions of 1-year THORN. Priced CATALOGUES may be had of Messrs. R. SILBERRAD AND SON, 5, Harp Lane, Great Tower Street, London, E.C.

The Best Hardy Bedding Plant.

CLEMATIS JACKMANII.—Flowers rich purple, 4 inches across, and so profuse as to completely cover the bed. Begins to bloom in June, and continues until severe frost. It is perfectly hardy, and the stools improve annually. The only secret of success is a rich soil, to keep up free growth. Strong plants in pots, 12s. per dozen; extra strong plants, 2 years old, 18s. per dozen. Other sorts of Clematis and Climbers in great variety. Descriptive LIST on application. RICHARD SMITH, Nurseryman, Worcester.

HEATHERSIDE NURSERY, Between Farnborough and Bayswater, Surrey. The attention of Gentlemen and others is called to the large and varied stock of CONIFERS, Hardy, Evergreen, and Flowering SHRUBS; Trained, Pyramid and Standard FRUIT TREES; Forest and Ornamental TREES, ROSES, &c.; Hardy CLEMATIS and VINES, &c., in Pots, at low and reduced prices. Priced CATALOGUE sent post-free. Address, HENRY SHELPERD, Manager.

POPLAR, canadensis nova, 12 to 20 feet high.
 These Trees have been grown expressly for Street and Avenue Planting.
 They are to be seen growing at Knap Hill, and are, without question, the finest stock of their kinds to be found in any Nursery in Europe.

ANTHONY WATERER,
 KNAP HILL, WOKING, SURREY.

PICEA CONCOLOR VIOLACEA.

Of this beautiful and distinct Rocky Mountain SILVER FIR we are glad to be able to offer established Plants, received by us, direct from its native habitat, two years ago. Whilst possessing some resemblance to P. LASIOCARPA our plant is thoroughly distinct, the leaves being rounder or needle-like in form, and verticillate rather than pectinate. The colour also is of a uniform silvery glaucous hue, both above and beneath, and is very aptly described by the name it bears. To all cultivators of the choicer Conifers, or Planters for Landscape effect, this must prove a valuable introduction.

- Plants in Pots, 3 to 5 inches high 10s. 6d. each.
- Plants in Pots, 5 to 7 inches high 15s. Od. ,,
- Plants in Pots, 7 to 10 inches high, bushy .. 21s. Od. ,,

JAMES BACKHOUSE & SON, THE NURSERIES, YORK.

Our Collection of CONIFERÆ and other ORNAMENTAL TREES is extensive and fine, the Plants as a rule being well-grown and well-rooted.

AMIES' CHEMICAL MANURE.

USED BY THE ROYAL HORTICULTURAL AND BOTANICAL SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.

PREPARED IN A FINE, DRY, INODOROUS POWDER.

Price, £12 per Ton; 15s. per Cwt.; and in Canisters, 1s., 2s. and 4s. each.

Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to

AMIES' CHEMICAL MANURE CO. (LIMITED), 79, MARK LANE, LONDON, E.C.

DRACÆNA GOLDIEANA.

One of the most magnificent ornamental-foliaged plants ever introduced, and altogether unique in character and aspect. It is a native of Western Tropical Africa. The plant is of erect habit, and the stems are closely set with stalked spreading leaves, the petioles of which are of a grayish colour; the blade of the leaf is cordate-ovate acuminate, with a yellowish-green costa, and marbled and irregularly

banded with dark green and silver-gray in alternate straight or furcate bands, the colours being about equally distributed. The back of the unfolded leaves is a pale reddish purple colour. It is without doubt one of the most superb of ornamental stove plants, and indispensable in all first-class collections.

Price, 7 and 10 Guineas each, according to size.

N.B.—THE FIVE-GUINEA SIZE ANNOUNCED LAST WEEK HAVE ALL BEEN SOLD.

BOWENIA SPECTABILIS SERRULATA.

This is a most distinct and remarkable plant, *Bowenia* being the only known Cycad having bipinnate fronds. It has a short thick caudex, from the crowns of which are developed its large and singularly handsome leaves. The petioles are long, slender, roundish, and of a dark green colour; the lamina is bipinnatisect and spreading, the

pinnules are firm in texture, obliquely falcato-lanceolate with an acuminate point, differing materially from the normal and only other known *Bowenia* in having their margins distinctly and prettily toothed or serrated. Any description must fail to give an adequate idea of the distinct and striking character of this ornamental Australian plant.

Price, 2 Guineas each.

 *Mr. WILLIAM BULL* has much pleasure in offering the above Plants, which are two most remarkable introductions, and from their sterling merit two of the greatest acquisitions he has ever had the pleasure to announce.

WILLIAM BULL, F.L.S.,

Is also offering the following NEW PLANTS:—

ARALIA FILICIFOLIA
COLEUS PICTUS
CROTON HENDERSONI
CROTON REX
CURMERIA WALLISHI
DIEFFENBACHIA CHELSONI

DIPLADENIA REGINA
DIPLAZIUM ARNOTTII
HIBISCUS (ROSA-SINENSIS) COLLERII
IRIS ROBINSONIANA
PANAX LACINIATUM
SADLERIA CYATHEOIDES

SMILAX SHUTTLEWORTHII
SIX NEW DRACÆNAS
TWENTY NEW DOUBLE-FLOWERED
IVY-LEAVED PELARGONIUMS
NEW REGAL PELARGONIUM—PRINCE
OF WALES.

For Descriptions and Prices of the above, and various other New Plants, see Mr. W. B.'s Illustrated Catalogue, price 1s.

ESTABLISHMENT FOR NEW AND RARE PLANTS,
KING'S ROAD, CHELSEA, LONDON, S.W.

For the best List of Choice Hyacinths, Tulips, Crocuses, Narcissus, &c., see our Beautifully Illustrated

CATALOGUE OF DUTCH FLOWER ROOTS FOR Autumn, 1877,

Containing numerous fine Engravings and much Valuable and Original Information on the successful Culture of Bulbous-rooted Plants. Should be read by all intending purchasers before ordering. Post-free on application.

Our 21s. Collection (No. 7).

For outdoor or open border decoration, contains the following liberal assortment:—

- 25 Hyacinths, choice mixed
- 18 Polyanthus Narcissus, mixed
- 12 Narcissus Poeticus double white
- 6 Campanelle Jonquils
- 25 Anemones, fine double
- 25 " fine single
- 50 Persian Ranunculi, mixed
- 5 Turba Ranunculi, in 4 varieties
- 150 Crocus, in 6 vars.
- 100 Snowdrops
- 12 Tulips, scarlet Van Thol
- 12 " Cottage Maid
- 12 " Yellow Prince
- 25 " double, mixed
- 12 " Rex Rubrum
- 12 " late, mixed
- 12 Scilla amœna
- 2 Lilium candidum
- 12 Spanish Iris
- 9 Herbaceous and Alpine Plants,

WITH FULL CULTURAL DIRECTIONS.

Case, Packing, and Carriage Free to any Railway Station in England and Wales.

Other Collections, for Greenhouse or Conservatory, &c., 12s. 6d., 21s., 42s., 63s., and 84s. each.

From Mr. H. BENNETT, Belle Vue Crescent, Clifton, Bristol. March 10, 1877.

"I am glad to tell you that the Hyacinths, Tulips, and Crocus I had in the Autumn have given entire satisfaction; the flowers are splendid."

From R. PRONCE, Esq., Ringgate, N.B. February 7, 1877.

"The Bulbs received from you in the Autumn have been particularly fine; some of the Hyacinths and Tulips now in bloom are large and beautiful, and have far exceeded any that I have had before."

DANIELS BROS., THE QUEEN'S SEEDSMEN, NORWICH.

Zonal Pelargonium, "New Life,"

First-class Certificate Royal Horticultural Society.

See H. CANNELL'S CATALOGUE, sent post-free, with full particulars of this invaluable Geranium, which gives quite a new feature to cut flowers, and will be eagerly sought after. It is now in full flower. Bloom sent free to any address for four stamps. H. CANNELL, Swanley, Kent.

TO THE TRADE.

JAMES & ROBERT THYNE

are now offering—

- ABUTILONS, in variety, in 3-inch pots, 9s. per dozen.
- ADIANTUM GRACILLIMUM, in 4-inch pots, 9s. to 12s. per dozen.
- ARDISIA CRENULATA, in 3-inch pots, 9s. per dozen.
- ARECA AUREA, in 3-inch pots, 70s. per 100.
- ARECA RUBRA, in 3-inch pots, 70s. per 100.
- CHAMÆROPS EXCELSA, in 3-inch pots, 30s. per 100.
- CICCA DISTICHA, in 4-inch pots, 12s. per dozen.
- CYRTODEIRA FULGIDA, in 3-inch pots, 18s. per dozen.
- COCOS WEDDELIANA, in thumb pots, 30s. per dozen.
- CROTONS, in variety, in 4-inch pots, 12s. to 18s. per dozen.
- CYATHEA DREGEI, recently imported and making magnificent heads, 6 feet stems, 12 guineas each; 5 feet stems, 10 guineas each; 3 feet 6 inches stems, 8 guineas each; 2 1/2 feet stems, 6 guineas each.
- CYPERUS LAXAS, in 4-inch pots, 6s. per dozen.
- DIEFFENBACHIAS, in variety, in 4-inch pots, 18s. per doz.
- DRACÆNAS, in variety, in 4-inch pots, 100s. per 100.
- IXORAS, in variety, in 3-inch pots, 12s. per dozen.
- LOMARIA DALGAIRNSIÆ, 10s. 6d. to 21s. each.
- PAULINIA THALICTRIFOLIA, in 3-inch pots, 12s. per doz.
- PHENIX RECLINATA, in 3-inch pots, 40s. per 100.
- " TENUIS, in 3-inch pots, 30s. per 100.
- PILLEA MUSCOSA, in 3-inch pots, 6s. per dozen.
- POINSETTIA PULCHERRIMA, in 5-inch pots, 9s. to 12s. per dozen.
- SEAFORTHIA ELEGANS, in 3-inch pots, 50s. per 100.
- SONERILLA HENDERSONI, in 4-inch pots, 18s. per doz.
- TACSONIA VAN VOLXEMII, in 5-inch pots, 6s. per dozen.

GREAT WESTERN NURSERIES, Kelvinside, Glasgow.

BEAUTIFUL FLOWERS

CHOICE COLLECTIONS

OF HYACINTHS, CROCUS, TULIPS, NARCISSUS,

&c., CONTAIN A

Superb assortment of the best varieties.

For Growing in Glasses, Pots, Vases, &c. 10s. 6d., 21s., and 42s. each.

For Outdoor Cultivation. 10s. 6d., 21s., and 42s. each.

For Greenhouse or Window Boxes. 10s. 6d., 21s., and 42s. each.

All Goods 20s. value Carriage Free.

Five per cent. discount for Cash.

The Queen's Seedsmen, WORDSLEY, STOURBRIDGE.

SATURDAY, OCTOBER 20, 1877.

HORTICULTURE AT MATLOCK AND DARLEY DALE.

A WEEK ago I set out from home for a short holiday, and I determined to make Matlock Bank my headquarters. Derbyshire is frequently supposed by those who know it only by name to be a rough, rugged, hilly, ungenial county, and "Stonyshire" (George Eliot's name for it in *Adam Bede*) is assumed to be a very just and appropriate *soubriquet*. And so in a sense it is; but it is something more, especially that part of it where I have passed my pleasant holiday. It is stony *plus* lovely vegetation. It is rocky, but clothed with beautiful and graceful alpine. Its very stone walls are covered with varied mosses, which enrich and adorn them. It is a county of natural rockeries, from which the student may glean many hints in building artificial ones at home.

The geology of the district is most interesting. At Matlock Bath, and all along the left-hand side of the Derwent as you walk towards Darley Dale, carboniferous limestone is the preponderating rock; on the opposite side of the river from Matlock Bridge sandstone or gritstone are met with everywhere. The characters of the hills on the two sides of the valley of the Derwent are consequently very dissimilar, not only in nature, but in appearance and products. It is chiefly to the sandstone side of the valley that I shall confine my remarks.

One of the first things which strikes the visitor is the cosy look of the houses, whether mansions or cottages, which are dotted over the wide-ranging landscape. The sandstone, of which most of them are built, after a few years' exposure, assumes a very pleasant neutral tint, which harmonises well with the rocks and their characteristic vegetation. There are very few cottages unadorned by climbers of some kind or other. Ivy is the favourite one, and I have noticed many lovely forms, the handsomest being a striking digitate variety which I have seen in several places. *Cratægus pyracantha* thrives amazingly, and I have rarely seen it so densely covered with berries as it is here. Its effect is much heightened by the background of dark grey stone in which it is trained. The same remark applies to the other climbers. *Cotoneaster microphylla* is a much used wall plant; occasionally one sees *Cydonia* (*Pyrus*) japonica, and *Clematis Jackmanni*, *Honeysuckles*, &c., and less frequently a *Euonymus*.

The cottage garden plots (I mean those in front of the cottages) are invariably occupied with old-fashioned herbaceous plants, while a few in which the owners have aimed at more display are less successful in the results achieved by means of *Pelargoniums*, *Calceolarias*, *Lobelias* and *Dahlias*. The prettiest gardens I have seen in front of cottages hereabouts are filled with hardy plants, and some of them are still (October 16) very gay with various coloured Clove Pinks. As to vegetable growing it is uniformly good. I have never before seen so many cottage gardens in any locality so well filled with green crops of first-rate quality. Scarlet Runner Beans have been most abundant and are still plentiful; Parsnips are excellent, so are Onions; while Cauliflowers and Cabbages are generally good enough for display at a village garden show. I was

gossiping with one of the cottagers of the district, and asking him if he was fond of his garden. "Well," said he, "I rather think I am. I took eleven prizes at last show." Potatoes are badly diseased. I yesterday saw a hard-working man getting up his crops, on which he had built expectations for a winter supply, and more than half were irretrievably gone.

Walking one day up among the hills I got to a little valley somewhat unexpectedly. It was warm and sheltered, though some 700 feet above the sea level. I came to a neat cottage garden, in which were a number of plants in bloom. Surely they must be Auriculas I thought. I came to a stand and looked again, and sure enough there were hundreds of alpine Auriculas, many prematurely in bloom, forced, no doubt, by the long-continued moisture and the recent warm weather. It was dinner-time, and I saw the cottager chatting with a neighbour, so I made bold to admire his taste. I found him quite an enthusiast. He said they were all seedlings, and he would not let me pass on until he had plucked me a number of beautiful trusses. I do not think I ever enjoyed alpine Auriculas so much, or had previously thought them so beautiful.

Another day I walked over to Darley Dale, bent on seeing Mr. James Smith's nursery. I went in the expectation of seeing a little country nursery, where I might probably find a few acres more or less occupied. Fancy my astonishment when I found, not one nursery, but many; not a few acres, but over 130, devoted entirely to plant and tree growing, situated in every possible position, and at altitudes varying from 500 to 1000 feet above the sea level. Although a perfect stranger, I met with that courtesy and hospitality which are so common with our nurserymen. Mr. Herbert Smith took me under his charge, and conducted me to as many of the nurseries as I could spare time to see. After a look round the home one, which is situated in that part of Darley called Two-dale (otherwise Toodle, or Toad-hole, as I found it was variously pronounced), and where I saw a large and varied collection of hardy Ferns, we proceeded along a rapidly rising road, with lovely hills on both sides, empurpled here and there with Heather, and golden with autumn-tinged Bracken, until, reaching a height of some 1000 feet, we came to a nursery of about 30 acres, humorously called by its owner "Siberia." I suppose I ought to visit it in January to realise the full force and appropriateness of the name. Here I found the most extensive and interesting collection of hardy Heaths I have ever seen. There are acres of them, and if I had seen nothing else, I should have been well rewarded for my walk. Of *Calluna vulgaris* I saw no less than twenty varieties, all robust, and many of them eminently beautiful. I must particularise a few:—*C. v. alba*, *C. v. Hammondii*, *C. v. rigida*, *C. v. Alportii* (crimson), *C. v. aurea*, a really golden-leaved kind; *C. v. flore-pleno*, the flowers like little balls; *C. v. Foxii*, dwarfier, and in every way superior to *pygmaea*. *Erica Tetralix Mackiana* was very distinct and attractive, *E. carnea* was just coming into bloom, and to see such masses as Mr. Smith has growing together in full bloom early in spring would be worth a day's journey. I was told that the firm will shortly be able to send out a pure white form of this valuable spring bloomer. But I must pass on. I can only state that I saw immense quantities of all descriptions of American and other bog plants, *Andromedas*, *Azaleas*, *Kalmias*, *Menziesias*, *Rhododendrons*, acre after acre, *Vacciniums*, and last, though by no means least, a goodly quarter of that useful berried covert plant, *Gaultheria Shallon*, of which I was told one gentleman planted 15,000 plants last year. Conifers of various kinds I found in most thriving condition, though in such an exposed and elevated

position. They are in almost as great profusion as *Rhododendrons*. I was told there was another nursery further on, but I was obliged to decline seeing it, as my time was short. So turning my face towards Darley, which we reached by a fresh route, we called at nursery after nursery, seeing others at a distance which I could not spare time to visit. I thus had a most unexpected treat. I saw almost every description of nursery stock grown at various altitudes, on different kinds of soils, and under varying conditions, and I returned to my lodgings with my ideas about hardy plant growing very considerably enlarged. *E. W. B.*

BEGONIA SPORTS.

Now that *Begonias* are becoming so popular, and are intercrossed so freely, we may expect to see some curious and valuable results in directions, perhaps, not wholly anticipated by the growers. Already we have double-flowered varieties, of which Messrs. Laing & Co., of Forest Hill, and Messrs. Henderson, of Maida Vale, have at various times kindly furnished us with specimens. In these the stamens of the male flowers have been completely, or almost completely, replaced by petals as regularly as in a *Ranunculus*.

While double-flowered varieties are thus assured certainties, some specimens with which we have been favoured by Mr. Swan, of The Gardens, Fallowfield, point to the possibility of our having a race of *Begonias* with the leaves and bracts coloured as brilliantly as those of the *Poinsettia*. The history of Mr. Swan's specimens is given in the following words:—

"The plant in question was raised from seed two years ago, gathered from amongst several tuberous *Begonias* which I had hybridised and sown soon after the seed was ripe. A number of plants came up and last summer flowered. This summer they are again in full bloom (July). The one from which the blooms were taken grew very freely, but no stronger than several of the others; but all last season, though it showed flowers of both sexes, it never opened one of the male blooms. As soon as the male flowers came to within about a day of opening they invariably fell off. This summer the plant is about 2 feet high by 18 inches through, and has shown flower very freely, and again only the female blooms open. I send you a spike with two flowers upon it. The male blooms fall until the largest of those I send appeared, when, instead of being a perfect bloom, it presented the singular appearance you will observe in the specimen. It seems to show a tendency to run into leaf, and then again it has thrown out fresh spikes, which are bearing flowers of both forms. Since the first one assumed this form another has appeared, which I also send."

In a subsequent letter Mr. Swan says: "I find that several more have since appeared on various parts of the plant, and though not so strong as those I first sent, still they show a very peculiar tendency to continue growing from the centre of the flowers, and also to form leaves in connection with some parts of the flowers."

The examination of the specimens forwarded by Mr. Swan showed that what under normal circumstances should have been a male flower was here replaced by an aggregation of scales, some of which were partly leafy and partly petaloid, others completely petaloid. From the axils of some these leaves originated branches with coloured bracts and imperfect flowers. Considered teratologically, then, we have here a profliferous male flower with distorted and partly leafy segments. In the centre of this distorted flower are observable a few traces of stamens (one is shown in the illustration, fig. 95) and a branched inflorescence, the result partly of axillary, partly of median proliferation. It would be very desirable to encourage and fix this variety, as we should then have a race of *Begonias* as remarkable as the so-called double *Poinsettias*.

New Garden Plants.

LOMARIA DISCOLOR var. *BIPINNATIFIDA*, Müller. Fragn. Phytog. Australie, v. 121; *L. DOBROYENSIS*, Hort. Bull.*

This most beautiful evergreen Fern has been exhibited both by Mr. Bull and Messrs. Veitch & Sons, and has obtained First-class Certificates both from the Royal Botanic and Royal Horticultural Societies.

* Fronds bipinnatifid; both primary and secondary segments blunt, oblong, crowded; the segments of the abortive fertile fronds pectinately pinnatifid.

Mr. Bull's plant, grown from a small offshoot, has so far been more symmetrical in habit, the broader sterile fronds spreading from the crown, and what appear to be fertile fronds (being constricted like them) forming an elegant central tuft. These apparently fertile fronds have, however, in all cases proved to be abortive. The plants imported by Messrs. Veitch were older and stronger subarborescent caudices, and had a less formal mode of growth; but now that they are fairly established there can be no doubt of the identity of the two plants, which certainly take rank amongst the most ornamental of hardy greenhouse Ferns. Sometimes the abortive fertile fronds come broader in their parts than at other times, and they are then quite intermediate in aspect between the two extreme forms, or what one would at first sight call the sterile and fertile fronds.

These sterile fronds are fully 2 feet long and spread outwards in all directions; they are oblong-lanceolate, with a short dark brown stipes, the primary segments closely set, and the secondary ones densely developed, so that the parts overlap, except along the rachis when the secondary lobes are not developed. The fertile fronds, or at least those which simulate them, stand erect in the centre, and from the pectinate margins of the segments have a very elegant appearance; their barrenness perhaps renders the plant all the more ornamental, as there is no deposit of spore-dust such as occurs on many plants having the same general habit. This species of *Lomaria* comes from Australia, whence also the variety *bipinnatifida* has been imported—Messrs. Veitch's plants from Melbourne. Dr. Mueller's specimens were gathered in the neighbourhood of the Bunip-Bunip Creek, and also on the Dandenong Mountain *T. Moore*.

CATASETUM PHASMA, n. sp.*

This is a queer plant, standing between *Catasetum sanguineum* and *gnomus*, but much nearer the last, which has been kept in good health several years in Hamburg garden (which is regarded now-a-days as quite exceptional, though in my youth the *Catasetum* were very common, quite persistent, and free-flowering in the stoves at Dresden under the management then used). It is very easily distinguished by the erect limb of the side lobes of the lip, which is nicely serrate. The callosities inside the lip and the middle lacinia too are very distinct. It bears a rich raceme of rather large flowers. Sepals and petals dark green, with numerous purplish brown spots. Limb of lip white; internal thickened limb of lip also white. Column light green, with numerous brown spots. It has just flowered in the Hamburg Botanic Garden. It was obtained with Eastern Brazilian species. *H. G. Rehb. f.*

THE BAGSHOT NURSERY.

MESSRS. JOHN WATERER & SONS may consider themselves fortunate men in having their famous American nursery situated in a locality which, according to the testimony of the late Sir James Clark, is the healthiest in Great Britain; and in having, in addition to great climatal advantages, a soil—light and sandy—which, if properly used, is in all respects so admirable for the rearing of a very wide and comprehensive range of arboreal subjects. That so enterprising a firm should have taken full advantage of such favourable circumstances is only what one would expect, and consequently we were not surprised to learn, on a recent visit, that they have now some 260 acres under nursery cultivation, besides about 120 acres of farm land, all of which, we believe, at some time or other have been reclaimed from "the Bagshot Sands." The firm, too, has always considered itself fortunately situated as to railway accommodation, being within easy reach of Sunningdale on the London, Wokingham and Reading line, Farnborough on the South-Western, and Blackwater on the South Eastern Railway systems; and we may now mention, for the benefit of future visitors, that a station will shortly be found even nearer at hand, in fact on the Messrs. Waterer's own land—the new station being on the Ascot and Aldershot line, now under construction and nearing its completion, which runs through the nursery.

The one great speciality of the nursery is, of course, the *Rhododendrons*, which are counted, not by hundreds, but by thousands, and if we said by tens of thousands we should not be far wide of the mark. They may be seen here in all sizes, from the grafted plants in pots to enormous bushes with heads measuring from 25 to 30 feet in circumference, and which lift with balls of earth

* *Catasetum phasma*.—(Aff. *Cataseto gnomo*).—Labelli lobis lateralibus semiovatis erectis minutissime ac densissime serratis, lobo antico minute triangulo, calcaris conico, ovarii pedicellati tertium aequante, callo obtusangulo utrinque intus in pariete superiori sub limbo lobi lateralis. *H. G. Rehb. f.*

FIG. 95.—A CURIOUS SEEDLING BEGONIA.

weighing from 10 to 15 cwt. each; to say nothing of thousands of standards 3 and 4 feet in height, and measuring anything from 2 to 30 feet in the circumference of their heads, all healthy and cleanly grown, well set with flower-buds, and, what is of more consequence to the purchaser, all short-jointed and wiry, the indelible mark of careful and systematic transplanting. This regular transplanting of large nursery stocks is an enormous and costly work to the grower, but it pays for doing, and so it is done as a matter of course, but nowhere better than we have seen than in the Surrey nurseries—not the Bagshot one alone. There's no mistake about it, the Bagshot soil does grow Rhododendrons, and you find them here in marvellous quantities; and what a sight they are in June! Wonderfully floriferous, wonderfully diversified in colour, and equally as wonderful their numbers—the land is clothed

in the leafy month with a beauty all its own, that any one may see for the trouble of going there, but which few, we imagine, would care to describe, and certainly we shall not attempt to do so. It is more interesting to us to hear Mr. John Waterer draw on his remarkable stock of Rhododendron lore—to hear that the first Rhododendron that was introduced was the pink-flowered *R. maximum*, which came from North America in 1756; that this was followed in 1763 by the extremely useful *R. ponticum*, from Armenia; and subsequently, in 1802, by *R. kamtschaticum*; in 1803, by *R. caucasicum*; and in 1809, by the fountain of all goodness in Rhododendrons—the beautiful North American *R. catawbiense*. The colour of the catawbiense flowers consisted of shades of rose or rosy purple, and it was eagerly sought after and bought up at high prices by various nurserymen. The nurserymen, and the Surrey men especially, pro-

pagated them with a will, and they soon became great favourites with amateurs on account of their bold flowers, fine foliage, and hardness of constitution. Some ten or eleven years after catawbiense arrived, and when it was becoming plentiful the magnificent crimson-flowered Rhododendron arboreum was introduced from Nepal, but the Indian subject was not hardy, and therefore an effort was soon made to turn it to useful account in another way, *i.e.*, by fertilising it with the pollen of catawbiense in the hope of raising a race of seedlings possessing the hardy constitution of the last named, and the rich colour of the Indian species. The result of the cross, as we all know, proved highly successful, and thousands of seedlings have since been raised, out of which have been selected the vast number of splendid, nay, gorgeously coloured varieties that now adorn our gardens. Each year has

seen the addition of several novelties to the list, and still they come, as if distinct varieties of this splendid race of plants were quite inexhaustible. Nowhere has this hybridising process been more actively carried on than in the Bagshot nursery, and Mr. John Waterer claims, as we believe with justice, to have produced more distinct and desirable novelties within the past ten years than were produced in all the years intervening from the date of the first cross. So much for the past. An inquiry as to what was being done in the way of novelties now elicited the fact that the Messrs. Waterer have half-a-dozen new ones to send out this season, and of which they think very highly. These are Duchess of Edinburgh, the flowers crimson with a light centre, and the truss conical-shaped; Duchess of Bedford, an enormous trusser, also crimson with a light centre; Kate Waterer, clear rosy crimson, with a large yellow blotch, very distinct; B. W. Currie, brilliant crimson with a light centre; Sir Arthur Guinness, clear rose, and large truss; and H. W. Punchard, plum-coloured, with a yellow centre.

All the named varieties are propagated by grafting, and the common stock for all is the well-known Rhododendron ponticum, which, when they have attained the proper size, are lifted from the seed-beds in the open air, potted up, and worked at once, the "saddle graft" being the style followed. After being grafted the plants are kept under glass until the scion and stock have united, when they are gradually inured to stronger air, and finally are transplanted in the open ground, and left there to take their chance of the weather. July and August are the principal months in the year for grafting, but some sorts can be worked later on, and others again in spring. From the time they are first planted out it takes from three to four years to get them up into saleable size, in the case of bushes, and from five to seven years in the case of standards; and many of the largest specimens in the nursery have taken from twenty-five to thirty years to attain their present dimensions.

Next to the Rhododendrons the most interesting subjects are the coniferous plants, all the best of which we found represented in large numbers and in plants of all sizes. Amongst Abies we noticed specially five quarters of amabilis, Douglasii, excolta, grandis (of Douglas), nobilis (a specimen tree of this grand Conifer, some 50 or 60 feet high, is quite laden with cones), Nordmanniana, and orientalis, together with Abies Engelmanni, in a quarter of which are several of the silvery-leaved variety. Several fine seminal varieties of Cupressus Lawsoniana were also brought under our notice, including one named argentea, which originated here, and is remarkable for its silvery hue; another, named aurea, also raised here, which has been certificated, and is a beautifully golden variegated plant; and, what may seem anomalous, a weeping form, named pendula. Of course most of the Lawsonianas are pendulous to a certain extent, but this is thoroughly distinct from any other in that respect, and a very handsome subject to boot. All the leading Pines may be seen here in great form, but we have not space to particularise them. We must note, however, before leaving these, the Bagshot variety of Thuja borealis variegata, a very handsome golden variegated new Conifer, which keeps true to its character, and does not burn. Out of all the plants that are growing here not one has had a branch burnt by the sun during the past summer.

Japanese plants are specially well done here, and to judge by the extraordinary rate at which they are being multiplied it would appear that the Messrs. Waterer had great faith in their future; and certainly, to see the various kinds as they grow here, a more beautiful lot of hardy plants can scarcely be imagined. That most of them are harder than the general public believe there can be no doubt whatever, and they are sure to make their way when better known. The Retinosporas, as they grow at Bagshot, are an especially beautiful tribe, and are to be seen here by the thousand, as well enough they might be. Handsomely grown specimens of Retinospora plumosa aurea stand in rows like pillars of gold—a truly beautiful sight—ay, and "they are as hardy as the common Yew," exclaims Mr. Waterer: a statement in which we entirely agree. Retinospora pisifera argentea and plumosa argentea are also both very striking plants, and equally so is the new Retinospora obtusa erecta now being sent out, and which is distinguished by its neat erect habit and bright green colour—characteristics sufficiently well marked to thoroughly well entitle it to the First-class Certificate which it has received. Small plants of these Retinosporas, together

with Osmanthus and other suchlike subjects, are becoming popular for winter bedding, for which they are eminently suited; and we noticed them planted out here as an illustration of the fact.

Great attention seems also to be paid to the rearing of standard trees of many popular subjects, besides Rhododendrons, such as Golden Yews, very striking ornamental subjects; common and variegated Hollies, and the famous Waterer's Golden Holly especially; Box, Portugal Laurels, Phillyreas, with very handsome, dense, close-growing heads; Guelder Roses, Scarlet Thorns, and Red Cedars, the latter trained into neat heads, on clean stems from 4 feet to 5 feet high. To these, of course, must be added such fine trees as Limes, Catalpas, Laburnums, Horse Chestnuts, and Spanish Chestnuts, Acers, Mountain Ash, Sycamores, Poplars and Tulip trees *ad infinitum*, which we need only mention.

Of hardy trees and shrubs and forest trees the Messrs. Waterer hold an enormous stock, but the usual character of such subjects is so well known that they need not be further alluded to, except it may be to pay a compliment to their fine thriving appearance. As regards the commoner kinds of shrubs, however, we should state that their numbers are legion. They are specially cultivated to the height of 3 or 4 feet; and of such subjects as Yews, Portugal Laurels, variegated Hollies, Aucubas, and Phillyreas, they are here in "drift" after "drift"—twenty, thirty, and forty thousand in each. Hollies are especially well done, and all the leading varieties are strongly represented, but none more so than Waterer's famous golden variety, which seems to be literally irrepresible. The Phillyreas are a grand lot. They are done well, and the larger specimens are particularly handsome objects.

A branch of the business which also claims a considerable amount of attention is the preparation and culture of several subjects for early forcing. The most popular amongst these, judged by the quantities of each under manipulation, appear to be various species and varieties of Andromeda, notably A. floribunda, Ghent Azaleas in colours, Rhododendrons, principally scarlet and white-flowered varieties; various Ledums, Kalmias latifolia and myrtifolia, Rhodora canadensis, Daphne Indica rubra and D. Cneorum, Hydrangeas Impératrice Eugénie, paniculata, and Otaksa; Deutzia crenata and gracilis, &c. Suitable subjects for planting in game preserves also form a feature in the establishment, and these we noted consisted in the main of the invaluable Rhododendron ponticum and seedling varieties of R. catawbiense, the excellent and free-growing Hardwicke variety of Box, the common Privet, and an oval-leaved variety, stated to be a strong and free grower; Berberis Aquifolium, which makes a fine cover for pheasants; the beautiful Cotoneaster Simonsii, the edible berries of which the pheasant is very fond of; Yews, common and Portugal Laurels, Hollies, &c.

The Messrs. Waterer & Sons have lately taken up the culture of Camellias on a large scale, and now annually propagate from 5000 to 6000 of that popular favourite—the old double white alone. We saw the young plants plunged out-of-doors in a sheltered situation, and a nice stocky, healthy-looking lot they were.

THE GENUS AGAVE.

(Continued from p. 398.)

53. *A. (Littæa) polyacantha*, Haworth; Jacobi, Monogr., p. 73; Nachtrage, ii., p. 83; *A. xalapensis*, Roelz; Jacobi, Monogr., p. 72; Nachtrage, p. 30; *A. uncinata*, Jacobi, Monogr., p. 104; *A. chiapensis*, Jacobi, Monogr., p. 235; Nachtrage, ii., p. 80.—Acaulescent. Leaves about 30 in a rosette, oblanceolate-spathulate, 1-2 feet long, 2½-5 inches broad above the middle, narrowed to 2-3 inches above the dilated base, where it is ¾ inch thick, bright green, slightly glaucous only in an early stage, the dark brown pungent end-spine ½-¾ inch long, and decurrent a little down the border, the crowded deltoid dark chestnut-brown irregular prickles of the margin ½-¾ inch long, all sub-patent, about half-a-dozen to 1 inch in the centre of the leaf, which is about ½ inch thick. Flowering-stem 8-12 feet high, including the dense spike, which is 3-4 feet long. Perianth, including the ovary, 1½-2 inches long; ovary oblong-trigonal, shorter than the greenish yellow limb; segments ¾ inch long, two or three times the funnel-shaped tube. Filaments more than twice as long as the segments; anthers ¾ inch long. Style reaching to the top of the stamens.

A native of Mexico, long known and widely spread in cultivation. I cannot make out that there is any material difference between the four plants of which I

have cited the names. It has often flowered, but has never been figured. It is marked in the group by the bright green colour of its leaves and crowded irregular deltoid-cuspidate brown teeth, the bases of which are quite confluent in the lower half or two-thirds of the margin.

54. *A. (Littæa) densiflora*, Hook. in Bot. Mag., t. 5006; Jacobi, Monogr., pp. 123-247.—Acaulescent. Leaves 30-40 in a rosette, oblanceolate-spathulate, 2-3 feet long, 3-5 inches broad above the middle, narrowed to 2½-4 inches above the base, where it is 1-1½ inch thick, slightly glaucous when young, bright green when mature, with a brown, slightly decurrent, pungent end-spine ½ inch long, ¾ inch thick in the centre, the crowded, deltoid, bright, chestnut-brown teeth ½-1 line long, the upper ones ascending, the lower spreading. Scape, including the spike, 6 feet long, the lower bract-leaves ascending, the upper ones spreading. Spike dense, 2 feet long; pedicels very short; bracts and bracteoles lanceolate. Perianth, including the ovary, 1½-2 inches long; ovary oblong-trigonal, ½-¾ inch long; tube funnel-shaped, ¼-½ inch long; segments under 1 inch long, falcate when expanded. Filaments inserted at the throat of the perianth tube, twice as long as the segments; anthers ½-¾ inch long. Style reaching to the top of the stamens; capsule oblong, 1 inch long.

A native of Mexico. It was described by Sir Wm. Hooker in the *Botanical Magazine*, from specimens that flowered at Kew in 1857. It flowered at Reigate in 1874, and at Kew as lately as the spring of 1877. It comes very near to *A. polyacantha*, but the texture of the leaf is softer, the colour is a brighter green, and the side spines are smaller.

55. *A. Salmidyckii*, Baker; *A. Keratto*, Salmidyck; Jacobi, Monogr., p. 127 and 249, not of Miller.—Acaulescent. Leaves 40-50 in a rosette, oblanceolate-spathulate, reaching a length of 4-5 feet, and a breadth of 5-6 inches above the middle, narrowed to 4-5 inches above the base, bright green, and for the group soft in texture, 1½-2 inches thick at the base, the brown sub-pungent terminal spine 1 inch long, the crowded minute dark brown deltoid-cuspidate spines of the margin a line long. Inflorescence unknown.

A native of Mexico. My description is taken from a very fine specimen which has been for many years in the Kew collection, and I have seen it also at Reigate. Miller's *Keratto*, as already stated, belongs to the group *Marginata*. This finishes the series of species of the group *Rigidæ*. *J. G. Baker.*

LITTLE KNOWN DAINTIES.

SALSIFY AND SCORZONERA.—That Salsify and Scorzonera are still cultivated in many large gardens may be known by the fact that stray allusions to their palatableness find their way now and again into horticultural journals. Yet appreciated as they are by the few they are really unknown dainties to the bulk of the population. Judging from the writings of the last century, Scorzonera and Salsify were articles of much more universal consumption among our immediate forefathers than they are with us; indeed, in that cosmopolitan emporium for edible vegetables, Covent Garden, it is to be seen in two or three shops only; and we might well say of it, as Curtis did of Seakale in 1822, "That we hope soon to see the plant so generally known that in future the markets of the first city of the world will be again duly supplied with this most desirable article."

Scorzonera has a history of its own. It was introduced into this country about 1576, and the origin of its becoming known as an edible vegetable is supposed to have arisen in the following manner, and, in fact, gave the plant its well merited name of Viper's Grass:—

"Scorzonera was first known on account of its supposed medical properties about the middle of the sixteenth century, in Spain, where it was esteemed as an antidote to poison of a snake called there *scorzo*. A Moor, it is said, who had learnt in Africa that this plant possessed so valuable a property, availed himself of the knowledge in effecting many cures with the juices of the leaves and roots upon peasants who had been bitten by these venomous reptiles while mowing; but he carefully concealed the plant, that he might retain to himself all the honour and the profit attendant on the discovery. He was at last observed to gather it among the mountains, to which the name of Scorzonera was then given from the name of the snake, the venom of which it was believed to render innocuous."

Salsify is so like Scorzonera, both in appearance and flavour, that the two roots are treated after similar culinary methods. Salsify was considered by Evelyn to be an English wild plant, with an Italianised name, evidently making no distinction between *Tragopogon pratensis* and *Tragopogon porrifolius*, although the former bears yellow flowers and the latter purple, yet even Evelyn speaks of Salsify, or Salsifix, as being "an excellent salet root."

The culinary preparation of these plants is exactly similar; they may be boiled, having been first scraped, and dished, when tender, on buttered toast, with good melted butter poured over; or, having been boiled, the roots may be mashed, made up into small cakes, and fried in butter; or they may, when cooked, be cut into lengths of about 2 inches, dipped in batter, and served as a *friture*. It is said that Scorzonera and Salsify are excellent when roasted, having much the flavour of Chestnuts, but of this mode of cooking I cannot speak from experience, but the delicacy of flavour when boiled has earned for this dainty the well-deserved appellation of vegetable oyster. *T. S. F.*

A VISIT TO THE BIG TREES OF AUSTRALIA AND CALIFORNIA.

To the European traveller in Victoria one of the chief attractions is, without doubt, the enormous size of some of its forest trees. Individual specimens were a short time ago reported to have been measured and found to attain a height of 500 feet or more, but the writer of this paper, having made enquiries in Melbourne as to the accuracy of this statement, was informed by the best authority in the colony that it had been made public under a misapprehension as to the reliability of the evidence on which it was based, and that, therefore, it had been retracted. But, notwithstanding the retraction, Victoria still lays claim, and with justice, to the possession of the loftiest trees in the world. Last year the writer had the good fortune to spend several days among the Mountain Ashes and White Gums at Fernshaw, and also to pay a visit to the Sequoias or "big trees" of California (commonly and erroneously called in England Wellingtonia), and therefore a few words about these, the most gigantic vegetable products of the Southern and Northern Hemispheres, may not be uninteresting.

THE AUSTRALIAN EUCALYPTUS.

Fernshaw is situated at a distance of some 45 miles to the north-east of Melbourne, in a little valley closed in by granitic mountains that rise, on one side at least, to an elevation of 4600 feet. The mountain slopes are steep, but not precipitous, and the soil that covers them is composed of the *debris* of disintegrated granite, mingled with vegetable mould, to the depth of several feet. Both valley and mountain side are densely clothed with magnificent trees, that seem to thrive almost equally well on the exposed slopes and in the protected hollows. In many places there is a dense undergrowth of Australian Hazel, through which it is difficult to force one's way, and which, by effectually preventing the sun's rays from reaching the ground, preserves the surface in a state of continual humidity. In other spots considerable groves of Tree Ferns are met with, and the village derives its name from this feature in the vegetation.

On taking up my quarters at the somewhat miserable little inn—the only one which the village possesses—I proceeded to question mine host as to the whereabouts and the dimensions of the biggest trees in the neighbourhood. I soon, however, found that his somewhat pardonable colonial pride in the natural wonders about him was so great and that he had no idea of putting any limits whatever to the magnitude of the trees and that 100 or even 200 feet was as nothing in his estimate of them. I thus gained some idea as to how the exaggerated stories about these trees had arisen, and if I had not made further enquiries I should probably have left the spot believing that many specimens were to be found of between 500 to 600 feet in height and over 100 feet in girth. On questioning the villagers, however, I found that not one of them would acknowledge that he had even seen a tree 400 feet long on the ground. I found too, that all the biggest trees in the neighbourhood were well-known and I had no difficulty in finding my way to them. I measured the girths of some that were pointed out as the largest, and found that in no case did they reach 40 feet, at a height of 5 feet from the ground, the girths of three of the largest being 38 feet

8 inches, 39 feet, and 39 feet 9 inches respectively. Two Sequoias, and these not the biggest in the Mariposa Grove, California, I found to be over 70 feet in circumference at the same distance from the ground. As the trees grow very closely together it requires a considerable amount of labour and care to take an accurate measurement of their heights; but from the fact that I stepped eighty paces along the trunk of one that was prostrate, which did not appear at all extraordinary in size, being only 5 feet in diameter, and from other considerations, I came to the conclusion that considerable numbers must attain a height of over 300 feet, but that none, at least in this neighbourhood, reach 400 feet. The chief feature of these trees, and in marked contrast with the "big trees" of California, is the extraordinary gracefulness of their stems. In the case of one of the tallest trees that I saw, probably considerably more than 300 feet in height, and the most graceful timber tree I had ever met with, the girth at 5 feet from the ground was only 13 feet. This tree had evidently been drawn upwards to the sunlight by the shade its neighbours cast upon it, and the trunk had through this cause been for a long time devoid of branches for about two-thirds of its length, until either accident or the axe of the woodcutter had let in the light, when many branches of foliage had burst from the stem, one or two of them being at no great distance from the ground. From the branches great lengths of bark were hanging, justifying the title which is sometimes applied to these trees, viz., "stringy-bark." They are, however, more commonly called "Mountain Ash"—their scientific name being *Eucalyptus obliquus*—but the same colonial names are so indiscriminately applied to different trees that it is often impossible to know what species is intended.

I was somewhat surprised to find wood-cutters licensed by the colonial Government hard at work cutting down any and every tree that seemed likely to repay the trouble of turning it into palings, and I was informed that already many of the finest trees had succumbed to their attacks. Only those that are too small or that will not split escape. It seems a pity that such beautiful scenery and such splendid forest—the capabilities of a most delightful summer resort—within a few hours ride by coach from Melbourne should be so unappreciated that the inhabitants do not care whether one of the most attractive spots in the colony is utterly spoiled or not.

On the flats along the banks of the Watts River, and within two miles of Fernshaw, may be seen a number of White Gums, so called on account of the whiteness of their bark, which have been considered by some to be rivals of the Mountain Ash. The largest of these trees that I could find measured only 25 feet in girth, and was not much if at all over 200 feet in height.

Since writing the above I have received a communication on the subject of the "big trees" of Australia from Mr. Ellery, the Government astronomer at Melbourne, and through him from Baron Von Mueller, to both of whom, for their ready kindness and assistance during my stay in Victoria, I have every reason to be grateful. Mr. Ellery, referring in his letter to a conversation with me in regard to these trees, speaks of "One measured near Mount Sabine, in the Cape Otway ranges, and selected from among numerous other giants to dispose of some doubts as to dimensions expressed by the late Professor Wilson, of our university. This one was 375 to 378 feet long from the ground to where the top had been broken off long before by the wind, the 3 feet being doubtful on account of the uneven nature of the ground at the base. It was estimated by our surveyors that 40 feet at least had been broken off the top, that is, it would have been 40 feet longer if the tree had been intact when it was felled. The average diameter just above the spurs or buttresses was 17 feet 3 inches, and 15 feet 3 inches where it was cut through for felling. This is not considered as one of our largest trees. In the Dandenong ranges, for instance, Baron Mueller got one measured which was 420 feet high, and I have this moment got the following from him in reply to an inquiry I made in order to be quite sure of his experience. He says, 'The highest Eucalyptus actually measured in Dandenong was 420 feet high, and I got one measured nearly as high at the Upper Yarra and the Upper Goulburn River, the trees being *Eucalyptus amygdalina* var. *reguans*. A Eucalyptus at Dandenong also was 295 feet to the first branch, and 365 feet to where the top was broken off, the diameter of the broken part being 3 feet.' Some higher measurements are on record, but

I doubt if they can be relied on. So much for 'big trees.' In Gipps Land, inland from Wilson's Promontory, there are the largest trees I have ever seen, but I have unfortunately no measurements yet."

It will be seen from the above that the "big trees" of Victoria overtop the Sequoias of California by about 100 feet, the tallest of these latter being only 325 feet in height. It will, too, I think be considered that the question as to there being trees in existence 500 feet high or more is finally and decisively answered in the negative.

THE CALIFORNIAN SEQUOIA.

The "big trees" of California are in marked contrast with those of Victoria. Forming along with the Redwood of the coast, a genus of their own (*Sequoia*), they are only to be found in isolated groves in the midst of the Pine forests on the slopes of the Sierra Nevada, and at a considerable distance from and elevation above the sea. Thus the Mariposa Grove contains 365 trees on an area of about 200 acres, at an elevation of 6500 feet above sea level, and at a distance of about 120 miles from the sea; whilst the Calaveras Grove contains between 90 and 100 trees on an area of about 50 acres, at an elevation of about 4700 feet above the sea, and at about the same distance as the Mariposa Grove from it. The Mariposa is the most southerly of the eight groves in which *Sequoia gigantea* is found. It contains by far the biggest trees as regards girth, the Big Grizzly, the largest of all, being 93 feet 7 inches in circumference. The loftiest trees, however, are in the Calaveras Grove, where four of the tallest attain to over 300 feet in height, viz., 325 feet, 319 feet, 315 feet, and 307 feet; these trees are 40 feet, 45 feet, 61 feet, and 47 feet respectively in circumference. The height of the Big Grizzly, the largest of solid timber trees, I suppose, in the world, is 260 feet, and one at least of its branches is 6 feet in diameter. The loftiest tree in the Mariposa Grove is 270 feet in height, and 81 feet 6 inches in girth. The former of these trees is terribly shattered at the top, either by wind or by lightning, as indeed are a great many in this grove, and their appearance as regards beauty of form contrasts most unfavourably with the trees around them—the Pitch and Sugar Pines (*Pinus ponderosa* and *Lambertiana*), the Douglas Spruce (*Abies Douglasii*), White Fir (*Picea grandis*), and Bastard Cedar (*Libocedrus decurrens*), the latter of which bears a considerable resemblance to the Sequoias, but is a much more elegant and perfect tree; indeed, the trunk of a *Sequoia gigantea* can scarcely be said to be beautiful in any sense, so far as regards its shape. It tapers regularly from the roots to the very top, and approaches in the form of its trunk so distinctly to a conical shape—as indeed is seen in many of the young Sequoias in England—that it is almost painful to the eye. The bark of the "big trees" is of an exceedingly rich brownish-red colour, which causes them to contrast strongly with the more sombre trunks of the surrounding trees. It is also very irregular, the vertical clefts in it, produced by the natural growth of the trunk, being often 12 to 15 inches in depth. The wood is remarkably light when dry, red coloured and very like Cedar. Some of the trees mentioned as associated with *Sequoia gigantea* attain a great height, indeed not far short of the tallest of the "big trees," and their trunks being not more than 8 feet or 9 feet in diameter their appearance is extremely elegant and beautiful.

The climate in which many of the "big trees" grow is one of wide variations, on account of the elevation of their habitat. In winter the snow is deep about their roots, and the cold is intense, on account of the rarity of the atmosphere. In summer the heat of the sun is equally intense, and the atmosphere exceedingly free from humidity, but the trees seem to have a vigorous vitality, and neither cold, nor fire, nor drought appear to injure them so much as the wind does.

It is a curious fact that the soil of the Mariposa Grove, in which the biggest of the trees are found, is granitic, and apparently resembles very closely that on which the big trees of Victoria are found. It may be mentioned that the only species extant that is closely allied to *S. gigantea* is *S. sempervivens*, or Redwood of the Californian coast. This tree, I believe, grows only within the limits of the sea-fogs, and thus forms a belt of irregular width along the coast for some hundreds of miles. It attains a height of close on 300 feet, and a circumference in rather a rare cases of 45 feet to 50 feet. Most of the houses in San

Francisco are built of the timber of this tree. *R. Abbey*.

Note.—The writer is indebted for most of the details given above to Professor Whitney's book on the Yosemite Valley. These details may be relied on as representing the only accurate measurements of the "big trees" that have ever been made.

FIGS, THEIR CULTURE AND COMMERCE.

The Fig tree produces a double and in some climates a triple crop, whence the great value attached to it in Eastern countries, where it bears fruit through a considerable portion of the year. The first ripe Figs come to maturity about the end of June, the second crop or summer Fig is that which is dried, the third often hangs and ripens upon the tree after the leaves are shed.

Two principal varieties may be distinguished—that which produces two crops a year, and that which yields but one. The former includes the grey or purple Fig, which is the best, the white Fig and the golden Fig, the latter being the finest in appearance, but not in quality. The main variety, which bears only one crop a year, supplies the greatest quantity of Figs for drying, among which the Marseillaise and Bellona are considered the best. The Barnissotte and the Aubique produce delicious large fruit, but they must be dried with fire-heat and are usually consumed fresh. The ordinary drying is effected in the sun.

There are two kinds chiefly worth cultivating, the true White Smyrna or Lisbon Fig, and the Black Fig, the fruit of which is purple from the skin to the core. The latter is much relished by beginners in Fig eating, because it is sub-acid and not so luscious as the white variety. Out of these, by hybridising, have come all the pinkish varieties, with names very various. The natural habit of the white Fig tree is to form a large open spreading tree, its great branches striking out at almost a right angle to the trunk, at a distance of from 8 to 12 feet. It is a handsome, rapid-growing tree, and a huge bearer. Of course it bears two crops—a very light one, numerically speaking, ripe in Portugal by June 24, hence called St. John's Figs. These are great coarse-looking things, of an indescribable colour, between dark red and green, and bear very little resemblance to the crop of pure white or golden-yellow, which do not come in until the middle and latter end of August. The second is the true crop, and usually one of such quantity that, despite all that may be gathered, thousands fall from the trees and are spoiled.

It is extremely difficult to form any estimate of the European consumption, but large as it is, it is greatly inferior to the consumption at the seats of production, especially in Turkey, where dried fruits form so important a part of the ordinary food of the people. In most countries the imports of dried fruits are summarised, so that it is impossible to separate or individualise the several kinds. Formerly when subject to duty Figs were separately enumerated by the Board of Trade, but now Currants and Raisins are the only dried fruits specified, and the consumption has doubtless increased since the removal of the duty. It may, however, be interesting to give an idea of the imports, which are nearly all taken for consumption here.

In 1840 the consumption here was not more than 40,000 cwt.; in 1855 the receipts were 44,725 cwt.; in 1860, 92,109 cwt.; in 1866, 95,721 cwt.; and in 1870 (the latest year for which we have official details), 106,504 cwt. were received: upwards of £152,000 being paid for this fruit. Our supplies come almost exclusively from Portugal, Spain, and Turkey.

The imports of Figs into Great Britain from Turkey have been as follows of late years:—

	Quantity.	Value.
	Cwt.	£.
1870	67,543	127,944
1871	73,755	135,751
1872	92,659	172,826
1873	80,421	177,408
1874	63,214	136,662
1875	96,629	213,615
1876	138,936	285,398

This is three times the quantity we used to receive fifteen years ago. From Spain we only receive a few thousand cwt. of Figs, although in 1872 10,000 cwt., and in 1873 16,500 cwt. were imported.

The export of Figs from Greece ranges from

100,000 cwt. to over 200,000 cwt. per annum. In 1871 207,067 cwt. were shipped, in 1874 only 143,040 cwt. The crop of Figs at Calamata in 1874 reached about 8000 tons, at an average cost of £15 per ton, giving a value of £120,000. The skin of these Figs is very tough, so that only small, indirect shipments are made to England; the bulk being sent to Russia by the Black Sea, or to Trieste for consumption in Germany. Figs are the object of an extended commerce in Asia Minor and the South of Europe, and the varieties are very numerous, including the Calamata of the Morea, the Fracazzani of the Ionian Isles, the small varieties of Dalmatia and Istria, and the large yellow of Genoa, the red of Sardinia, and those of La Pouille, Calabria, and Sicily. The finest, however, are generally those of Spain, Portugal, Turkey, and France. They are grown about Malaga, Seville, Alicante, Adra, and Valencia. The large "coroadres" of Algarva are surpassed by those grown at Aidin, Cyprus, and Aleppo.

Many varieties of the Fig are cultivated in Sicily; the dried Fig is exported. The Fig tree springs up in every soil, but it prefers a somewhat calcareous and rocky ground. The wild Fig tree grows on old walls, in the crevices of rocks, &c. It is evidently quite indigenous.

The centres of production in France are Ollioules, Ciotat, and Cadere, where the Marseillaise kinds known as "peloises" are grown; Toulon, Cuers, and Salurs, where the large white Marseillaises are produced; Salernes, noted for its fat Figs; Roquevaire, for its large bluish species, with their skin and red flesh; Antibes, Frejus, Grasse, and Cannes, for their "bellonnes," "mantegrasses," and "meselisses"; and finally, those grown at Comtat, in Avignon, known as "blanquettes," of which there is a large export to Bremen and Hamburg. The Figs of Dalmatia and Istria are small, of a round form, slightly elongated, of an excellent flavour, but will not keep well.

The Figs of Smyrna, so much sought after in Europe and America, come chiefly from the plains of Aidin. The quantity which is raised annually at Smyrna to be sent to foreign countries may be taken at 26,000,000 lb., of the value of £200,000. The shipments to France, which in 1872 were only 416,000 kilos., of the value of 302,000 francs, in 1873 rose to 765,000 kilos., of the value of 445,000 francs. The whole valley of Aidin, from Naslii to the sea, produces Figs of the finest quality. These are divided into two classes, "elemé," or those picked by hand, and merchants' Figs. There is a smaller sort sent to Scala Nuova for the Greek islands. The Sugar Fig, or "Sheker-injury," is used for eating first, as it will not preserve for export. *P. L. S.*

AERIDES CRASSIFOLIUM.

WE have to thank the Messrs. Veitch & Sons, of the Royal Exotic Nursery, Chelsea, for the opportunity of illustrating (fig. 96) this rare Indian species, which Professor Reichenbach characterises as "the king of all the *Aerides*." It is a dwarf, dense-habited plant, with broad, thick, purple-dotted obliquely-bilobed leaves. The flowers, which are borne on long and drooping spikes, are large—larger than those of *A. falcatum*, which they resemble in form, and have the segments tipped with rich purple or smethyst, the centre or throat of the flower being ivory-white. The plant is one of the many fine subjects introduced from India by the Rev. C. Parish, and appears to have been first flowered in this country by R. B. Dodgson, Esq., of Blackburn, in 1873, as recorded at p. 633 of our vol. vii., new series. It appears to come near *A. falcatum*, since Professor Reichenbach hesitated to receive it as a species until he had seen living specimens, by the aid of which he was enabled to pronounce it as distinct (see vol. vii., n.s., p. 590). Compared with *A. falcatum*, the spur is here bent under at an angle, while in that plant it is straight; the side lacinix of the lip are much broader and shorter in the present plant, and the two keels on the lip here stand close together at the base, and become divergent, whilst in *falcatum* they are distant at the base and become convergent near the middle of the lip. These technical peculiarities may serve to facilitate its recognition, while from its ornamental qualities it cannot but be much sought after. The Messrs. Veitch obtained a First-class Certificate for the plant of this species shown by them at the meeting of the Royal Horticultural Society at South Kensington on July 3, and which is represented in the accompanying woodcut.

Natural History.

SHOOTING WILD BIRDS.—That my remarks upon the cruel practice of wantonly shooting rare wild birds have provoked replies from two correspondents who claim to be sportsmen is so far satisfactory, inasmuch as it shows that the shot told home. The assumption that there is a connection between rare birds and game is simply absurd. Game birds are food, and in a small way form part of the food supply of the nation—they are in fact preserved to be shot, whilst rare birds would seem to be shot to be in a different sense preserved. All lovers of Nature who have in their breasts other feelings than a mere selfish desire to possess a choice collection of stuffed birds, will agree with me that the wilful and wanton destruction of rare and beautiful wild birds is deserving of severe condemnation. Only recently, when the foolish fashion of wearing birds in the headdress by ladies was so prevalent, an universal condemnation of the practice arose from the Press, because it led to their possible entire destruction. Of course it was "maudlin sentiment," but that sneer is ever flung by the ignorant at humane efforts. A "Subscriber" is exceedingly unfortunate in his exhibition of anatomical knowledge. The human mouth is almost the widest possible removed in living Nature from that common to the carnivora, whilst it is most nearly allied to that despised race of beings which is naturally strictly frugivorous—the monkeys. Our lords of the creation who carry guns will perhaps hardly relish that unhappy fact, but such is the case despite the teaching of "Subscriber." In conclusion, let me invite your correspondents to give a short time to studying the *Essay on Man* by that celebrated poet and philosopher, Alexander Pope, as in it they will find these lines—

"Is it for thee the lark ascends and sings?
Joy tunes his voice and elevates his wings.
Is it for thee the linnet pours his throat?
Loves of his own and raptures swell the note."

A. D.

A PET GANDER.—I have read of numerous kinds of pets, have seen many, and must confess my own weakness in having possessed many such. My first attentions were devoted to toads, and very few persons can believe how much an unprepossessing creature of this kind can be taught. I had five; they knew me perfectly, they knew their own names, &c. I believe there is hardly any bird or animal that will not show some recognition when submitted to a treatment of kindly attention. Until lately I had never seen a gander reformed into a decent member of the community; but I have seen one quite a gentleman in everything but his voice. That is loud, but not sweet, and he will speak out of his turn; but he walks about with his master, comes with him into the town, looks into the shop windows as he proceeds, and makes sundry remarks in his own language, which is unfortunately not intelligible to us. But he seems to be thoroughly attached to his master, and to enjoy his presence. *William Payne, Taunton.*

COLIAS EDUSA.—The clouded yellow butterfly, *Colias Edusa*, has been very abundant this autumn in this neighbourhood (Ealing). I never remember to have seen it so plentiful in any preceding year. *E. T. M., Ealing.* [Also most abundant at Richmond (*W. F.*), and generally near London, and in Northern France. *Eds.*]

The Villa Garden.

AUTUMN IS HERE.—How rapidly, and almost imperceptibly, the deep green of the matured summer leaf foliage on the trees changed to the decaying golden red and orange tints of the autumnal season. A sharp frost or two wrought the change, hastening the decay, just when we were hoping soft, balmy, sunny weather would repay somewhat the loss of much of the glory of the summer. But it is not to be.

"Through the tall trees the biting wind blows keen,
Whirling the dead leaves from their summer bowers;
Not singly, but in clouds they now are seen,
Piling up graves above the faded flowers."

And so the summer of 1877 passes away, and is numbered with the things that once were.

EXTERIOR WINDOW BOXES AND PLANTS.—Alas! the glories of these have in a great many cases long since faded. A great deal of the exterior window gardening of London is of an evanescent character. During May and June the aspect is one of pleasant effectiveness, and then London society, like a bird of passage taking its annual departure, flits away to other scenes; the shutters are closed, the houses well-nigh deserted, and in a few weeks exterior window-boxes become sad and sorry sights. One is sometimes tempted to climb the area railings, and give the plants the water so much needed at the roots, or haul the miserable-looking boxes down into the area below, so offensive are they to one's notions of the fitness of things. A kind of lamentable wail appears to go up from the neglected plants as in

appearance, while Pelargoniums have their leaves either sere and yellow, or else spotted or riddled by green caterpillars. Where these little ravaging Bashi-Bazouks of the insect world come from is to many a matter for wonder, but there they are, in Cavendish Square and Bethnal Green alike, to the sorrow of window gardeners.

These little brisk evergreens suitable for winter decoration can be grown planted out in boxes or in pots. They are very accommodating, if kindly considered. If neglected, they resent neglect, and take on a melancholy cast of leaf expression. Plants are social beings, and are impatient of the cold shoulder; and with true instinct pine away and decay, and presently "the languid waste of life" is found *in articulo mortis*. Area-courts are sometimes nearly

loosely and in an unworkmanlike fashion. A crotchety in a respectable nursery would have stood appalled at such a spectacle. We were asked if we wanted to buy, and by a supreme effort withheld speech and passed on. Many of these plants will exist, a few may flourish, but the imperfect work seen in the potting must operate as a disadvantage to plants grown in London windows.

Mr. Wildsmith, of Heckfield Place Gardens, and others have shown us how much harassing these plants will stand when used solely for winter gardening. Planted out in beds at the end of October, and lifted again in the middle of May, and placed in nursery plantations for the summer, the plants yet keep fresh and nice; they make but little growth, because the roots are trimmed a little at each time of planting, and if they

FIG. 96.—AERIDES CRASSIFOLIUM.

sorrowful protest against so much cruel disregard. People who do their gardening in this sorry fashion have missed the enthusiasm which respects and ministers to the wants of plants.

Boxes of the usual flowering plants have had a bad time of it, even when well attended to, the sun was chary of its invigorating, brightening beams, dull weather can hardly be anything else than hostile to London gardening. In all probability the plants are scarcely hardened off enough before being placed in the boxes; and by the time they have recovered the effects or the check, the summer is advanced and the floral service is necessarily short. Any one walking about the London streets can hardly fail to be struck with the great advantage of the hardy evergreen plants we have so often advocated as most deserving of use for filling window boxes. *Ancuba japonica*, for instance, is bright with variegation, and clean and effective in

brimful of such plants, that look as if they were vegetable suicides starving themselves to death.

The London costermonger, knowing that the summer denizens of window-boxes are *in extremis*, is already hawking about the streets small specimens of evergreens in pots. We inspected a barrow of these recently in Connaught Square. There were *Rhododendrons*, *Bays*, *Aucubas*, *Euonymus*, *Box*, *Retinosporas*, *Thuja*, *Arbor-vitæ*, &c., on the whole nice little stuff, brought from nurseries and potted up for sale. But such potting! It must have been the coster's own handiwork: the rough had left his own impress on the performance. The pots must have been a cheap lot; they were of divers patterns and various sizes, uncouth in build, and seriously chipped on the edges of the rims. The soil looked as if it had been purloined from some hedgerow not the freehold of the operator. It was thrust in about the roots

do grow out somewhat they bear cutting back with perfect equanimity; and in the case of being planted in exterior window boxes they might be replanted each year in autumn—say, in October, placing some good soil about the roots, trimming them as necessary, cutting back a leading shoot here and there, and pressing the soil firmly about the roots. A box of sufficient width—say, 15 to 18 inches inside—might be made in two divisions, with a partition running lengthwise. A space of 8 to 9 inches in width might be given at the back for evergreens, and another of 4 or 6 inches in front for a few bulbs, *Primroses*, &c., for winter and spring; and a few suitable flowering plants for summer. In planting the evergreens a little care in mingling habit of growth, shape, and character of leaf, &c., would secure a pleasing effect, varying to some extent with the season of the year. There need be no mere uniformity. There is play for the skill of

the artist in arranging a window-box of plants. That quaint old poet, Herbert, wrote :—

“ Who sweeps a room as in Thy sight,
Makes that and the action fine.”

Common things may be refined by the touch of genius, and the genius is not unkindful of the lowly. A window-box may just as well be a pretty, pleasant picture as its inartistic and undesirable reverse.

Foreign Correspondence.

CANADIAN NOTES.—The late summer was a very hot one (with the thermometer ranging in July sometimes 87° in the shade and 110° in the sun), and also extraordinarily dry, and the power of the winter Wheat to flourish with a small quantity of rain has once more been satisfactorily proved, inasmuch as from the time the snow left us in April until July 31, when the reaping commenced, we had not more in the amount of fall than three days' rain, and yet the harvest was exceptionally abundant, except on low grounds, where an unusual frost inflicted considerable damage. The spring crops, however, of course suffered materially for want of moisture.

It may not be uninteresting to direct attention to the rapid growth of plants here, as compared with England, as shown in the progress of the winter Wheat sown at the end of August and the beginning of the present month, which in every instance made its appearance on the fifth day, was up on the sixth, and nicely out of the ground all over the fields on the seventh day after sowing. A similarly proportionate speed of growth takes place generally also in the Grape vines.

Our gardens are affording us an abundance of Grapes and Plums, of Potatoes and Indian Corn, of Citrons and Pumpkins, and of Cucumbers, Melons, and Tomatos. Apples, with the exception of Crabs, are a casual crop, and many orchards have scarcely any.

There seems to be a great deal of difference of opinion on your side with reference to self-sown Potatos. We happened to have a good many on some new ground, and they turned out to be the earliest and finest we had on that description of soil, which is a fine sandy loam. Our crops of Potatos are better this year on clay loam, as they have stood the drought nicely.

It has been an amusing and pleasing spectacle for some time past to see the children coming from the woods and lowlands, loaded as heavily as at all practicable with Butternuts, Grapes, and Elderberries, all of which are exceedingly plentiful this season.

We were much surprised on reading a recent issue of yours to find that Italian Bees are scarcely in fashion with you yet, as they have been gaining ground here these two years past; and now most of the apiarians have supplied themselves with queens from the United States (at prices varying in the spring and fall of the year from 4 dollars to 1 dollar each respectively). For the benefit of those who have not yet tried the Ligurian bee it may perhaps be as well to say that our experience as to its superiority over the common one quite agrees with that of your correspondent, as expressed in the article above alluded to. *John Morren, Elm Farm, Minesing, Ontario.*

YACKANDANAH, OVENS DISTRICT, VICTORIA :

April 10. — During a recent trip up the Murray River the weather was extremely hot (about 100° in the shade). I had been in the saddle for some hours in the scorching heat, the perspiration was rolling freely from every pore, and I really felt as though I was getting gradually smaller and “beautifully less.” My eye naturally sought some place where I could fling myself on Mother Earth at full length and doff my tolerably broad-brimmed hat without fear of *coup de soleil*. I was unsuccessful in this respect; for fine a climate as we have, together with many other benefits, yet we are strangely devoid of shade trees. The shape afforded by the generality of native trees is not all that one could desire. Even some of our gigantic Gums, grand as they are as timber trees, afford but a poor retreat from the sun's rays, for really the only shade these trees give us is that thrown by the trunk, and this, of course, is all the time shifting round, so that if one, fatigued and heated, seeks protection here, and, as is often the case, falls asleep, he is apt to wake up and find himself baking, while the

shade he fell asleep in has shifted a yard or so on one side. But I am digressing. I said I was unsuccessful. I was so: but taking things as coolly as I could under the circumstances, I continued my way for a mile or so, when, upon rounding a point of the range, I saw what I had been so devoutly wishing for—shade, ay, and dense shade too. The road here was cut in the side of the range, which was steep and rocky, and just at the top of a steep grade, and at a sharp turn in the road grew in its usually peculiar place a Corrijong tree. To get off my horse, pitch my hat aside, and stretch out did not take so long as it does to write it.

The Corrijong is a peculiar tree in its choice of spot to flourish in. Wherever you see one growing there you will find rocks (I only know of one or two instances to the contrary), and really in some cases it seems part and parcel of the granite. A tolerably good-sized tree will grow out of an opening, a mere crack in the rocks, and as it grows it folds its wood over sharp edges and points, and seems as though it was unwilling to leave its rugged friend. Then as it grows and frees itself from the distorting influence of its birthplace its trunk assumes an uniform shape, and the branches alone represent above what it was below in point of knots and twistiness. The leaves grow in thick clusters close together, and afford a dense shade, and through which old Sol is puzzled to send a spark of light. The bark is, as nearly as I can remember, similar to that of the common Box (*Buxus sempervirens*), but of a darker colour.

Pardon this lengthy description, although I would I were better able to do more justice to a true friend in summer, and an ornament at any time. If it was only from the fact of its flourishing in such rugged places and on such apparent barrenness, one cannot help but appreciate it for its eccentricity.

I enclose a sketch of the leaf and seedpod. [A species of *Acacia* perhaps. EDS.] The flower I have neglected to obtain.

June 20. — Since I have been in this country it has always been a matter of regret to me, when noticing the scenery, to find so little variety in the foliage of the trees; and especially is it more marked when viewed from a distance. The configuration of the country where I am located is generally hilly. Looking from a higher range over the vast expanse of country that lies before you, though the hills are clothed with timber of four or five different kinds, yet their foliage is so similar that, but for an occasional glimpse of the blanched trunk of the Eucalyptus, you might take them all either for the Stringy Bark or the Messmate. Then it is that one sighs for relief.

I have often thought that if the trees of this country were not evergreen, but shed their leaves as the majority of European trees do, what a glorious sight our hilly country would be in the fall. But now the Poplar and Willow are common with us in settled parts, and it was during this last fall that I noticed more particularly how brilliant the yellow dying leaves of the Poplar looked against the indigenous tree-clothed hills as a background. But the Poplar does not deserve all the praise. The Vines, the Peach, the Quince, and other fruit trees in the gardens, all contribute their many tints to relieve the scene, to please the eye; and last, not least, to remind us of Old England's woods.

Then, again, how grand are our sunsets. I think one of the finest sights I know of is witnessing the reflection of the setting sun on the distant hills. Magenta is the only colour I can liken it to.

“ The sun from his golden bed
On the far-off hill-tops shed
Rays, amber and crimson-red,
And the day was almost dead.” C. E.

Since I have learnt to appreciate these pleasing effects, I have ceased to grumble at the sameness of our foliage. *Charles Edmonds, Jun.*

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—*Achimenes* and *Gloxinias*, the tops of which are now dead down, should be stored away for the winter with the soil in a completely dry condition. With beginners in the cultivation of these plants it frequently happens that an erroneous impression prevails as to the usage the roots should receive whilst in a state of rest, through which they are subjected to cooler treatment than they can bear. The result of this is that when examined at the time they are required to be started, they are found in a mouldy, rotten condition, or, if not quite dead, so weakened

that they are of little use. This treatment comes through a mistaken conception of the nature of the plants. It should ever be borne in mind that they are indigenous to hot countries, and, although in a dormant state through the winter, yet nevertheless their nature is in no ways changed under artificial cultivation; and that their roots, even when at rest, cannot bear a temperature very much lower than what they would receive in their native countries, especially when such a reduction of heat is made in company with any damp. The treatment we give these and many other plants, the tops of which die down in the winter, is directly opposed to that which they undergo in a state of Nature. In their native countries the rest often occurs during a season when the heat is as great, if not greater, than that which they experience whilst in active growth, rest being induced by the perfectly dried, parched-up condition of the soil, to such an extent, it may be said, as to subject them to a forced inactivity through an absence of moisture, such as prevents the possibility of active growth. A little reflection upon this will point to the treatment that in some measure we ought to imitate. Where there is room to stow the pots away, laid on their sides on a shelf, or in any position where they will receive no moisture, either directly or from absorption, in a temperature of from 50° to 55°, it will answer for them.

Caladiums, the leaves of which are now beginning to show discoloration, must have water gradually withheld, so as to induce the foliage to die down. The exact condition will in a great measure depend upon the time they were started in spring, the earliest grown plants, of course, being the first to lose their leaves in autumn. It is not well to withhold water altogether as soon as the cessation of growth indicates a disposition to go to rest, as where the drying-up process is carried out too quickly it kills the leaves at once, instead of submitting them to gradual maturation, from the effects of which the roots suffer, often shrivelling to a considerable extent, the result of which is they start weakly in spring. The roots of these also keep best in the soil in which they have been grown, yet, as in the case of the *Achimenes* and *Gloxinias*, where room is an object, they may be taken out of the pots and transferred to paper bags filled with dry sand so as to exclude the air from them, otherwise they will shrivel. Tuberous-rooted *Gesneras* of the *Cooperii* section that have been treated so as to induce their coming into flower early in the spring, will now be approaching a state of rest. They should be kept in the pots in which they are grown quite dry, and stored at the coolest end of the stove or intermediate house; these plants are of a most accommodating nature, and by the use of a sufficient number may be had in bloom at the opposite ends of the year, as by resting at a different season some can be had in flower from this time till Christmas. These late-grown plants should occupy a light situation near the glass, and be kept quite free from the insects that molest them, the worst of which are thrips and mealy-bug. Should they get affected with the latter there is no remedy but sponging, as the leaves are too soft to withstand the application of any dressing strong enough to kill the insects. *Gesneras* of the *Nægelia* section grown for winter flowering should have every attention paid them, so as to retain their finely-marked leaves in a healthy condition from the base upwards. Not only is this necessary to enable them to produce the full complement of flowers, but when a portion of the foliage is lost or becomes discoloured, half the beauty of the plants for decorative purposes is destroyed. From the hairy nature of their leaves, care should be taken that they do not get infested with mealy-bug, as any washing and sponging, however carefully performed, is almost certain to destroy their lustrous appearance.

The first-potted Roman Hyacinths, where their flowers are wanted early, should, as soon as they have made sufficient roots, be placed in a little warmth, and if possible where they can be plunged in a gentle bottom-heat, with their heads somewhat cooler and close to the glass. To effect this, I have found nothing so good as a hotbed made up of leaves and well sweetened manure, with 8 inches of old potting soil in a moderately dry state in which to plunge the pots laid on the top, covering the whole with a frame. Here the top-heat can be so regulated by the admission of air as to prevent the plants becoming in the least drawn, from which cause, if affected in this way, they suffer so as to spoil their appearance. By thus keeping the bottom-heat higher than the top the roots will be in advance of the leaves and flowers, thereby strengthening their blooming.

Summer flowering stove climbers, where grown on the roof, should now be cut in freely, to give as much light as possible to the plants underneath—rendered necessary by the shorter days and decreasing sun power. It is especially needful where considerable quantities of winter flowering subjects are grown. When such climbers are confined to the rafters alone, they do not so much affect the plants underneath, but nevertheless, all that are about completing their blooming may with advantage be freely cut in. Any

that have been affected with insects should be loosened from the wires, and immersed in a strong solution of insecticide, allowing them to remain in it for an hour or two, which will be much more effectual than syringing or the usual sponging, besides effecting a considerable saving in labour. Whatever is used for the destruction of insects may now be applied much stronger than when the plants are growing freely. Cuttings of stove plants put in to strike some weeks back will by this time be sufficiently rooted for potting off. They will require less root-room than spring-struck stocks, from the slower growth they will make through the winter time; but there is a considerable advantage with these autumn-struck plants, as they start off with the first increase of temperature in the early months, and keep through the season a good deal in advance of those that are struck at the other end of the year. *T. Baines.*

ORCHIDS.—Plants of the hardy section of *Cypripediums*, more particularly those of *C. spectabile*, must now be stood in the frames, where it is advisable they should remain during the winter months. This superb species, after flowering during the early summer months, should have been, as advised, set outdoors on an ash border in such a position that whilst receiving plenty of light they would not catch much strong sunshine, this causing them to dry so rapidly that they often suffer in consequence. The blooms being over, the remaining part of the season is taken up in ripening the growth already made, and the formation at the base of the old bulbs of a number of new buds that apparently remain dormant for several months, but which, under the influence of the genial warmth and moisture of spring, start again into life and growth, and in due time enrich our cool structures with flowers of a most interesting form, and at the same time rich and pleasant colours. The growths will now have died down, and should be cut off an inch or two above the soil, and on examining the surface a number of prominent eyes will be observed around the base of the growths. Every care must be taken of these, for when stood in the cold frames the slugs, which seem to have a special liking for everything that is choice, are very apt to get upon them and just eat off the top; this, of course, taking away entirely the next season's growth. A little dry lime spread on the ashes of the frame is a good preventive. Here they should remain till about March, when they may, by being moved into warmer structures, be brought on a little more quickly as they may be required. Whilst in the cold pit a few leaves pushed in amongst the pans, and also spread over the plants, will be of great service in protecting them from sudden and severe frosts.

Dendrochilum glumaceum, a plant that is usually grown in the East India-house, and started into growth early in the spring that it may flower by March and April, will be better just now if it is stood in the Cattleya-house. Here it should remain for about two months, and have less water given at the roots. This will insure the ripening of the growths made this season, and at the proper season cause the breaks to start away more freely, and at the same time in greater numbers. When, however, the buds are showing their rosy coloured points, it must again be stood in the East India-house; then as the growths push up, and the new roots that quickly follow enter the soil, the supply of water must be much greater, and a sprinkling overhead will help to keep down the red-spider, to which the *Dendrochilum* is subject.

Cypripedium Pierceli and *caudatum* in the Cattleya-house must now be well supplied with water, the latter more particularly just now growing very vigorously. In the warmer houses, *C. Stonei*, *Lowi*, *Parishii*, *villosum*, and the *barbatum* section, that are also in active growth, must not be allowed to suffer for the want of the same necessity. *C. insignis* will now in most cases be in flower; this may be grown very well in the *Odotoglossum*-house, but during the summer it is better for a little more warmth; the growths are stouter, the flowers are a little earlier, and of a larger size, than if it is grown altogether in a cool house. Several varieties of this are worth growing, *Maulei*, when it is obtained true, being very pretty; the most desirable, however, is *violaceum punctatum*, the size of the blooms and the bright markings of the sepals and petals giving this a most attractive appearance. This, however, is even more rare than *Maulei*. The collection now will require careful treatment in regard to moisture. An excess will cause damp and spot at the same time. If the stages and walks are kept too dry, thrips and red-spider will soon get into the hearts of the plants, and cause many a new growth to be permanently disfigured. Endeavour to ward off both evils. *W. Swan, Fallowfield.*

FLOWER GARDEN, ETC.

As soon as the bedding plants become unsightly and no longer fit to occupy the flower beds they had better be cleared off and wheeled to the rubbish-heap; or such of the sorts as are wanted as stock for another

season should be potted and stored away for the winter. Any contemplated alterations may be proceeded with. Trees and shrubs should be planted, and the work pushed forward with as much energy as possible, but I do not mean that the work should be carried on with undue haste, for nothing is gained by hurrying on work of this kind, where so much care is required in its being properly performed. All sorts of trees and shrubs should be lifted and transplanted with the greatest care, preserving as many of the roots as possible: nothing looks so unworkmanlike as to see a number of the best roots broken and mutilated—it is also injurious to the future well-doing of the plants. Wherever the roots are bruised in lifting they should be cut back to a sound part. Where the soil is not suitable for the healthy growth of the trees requiring to be planted good fresh material may be used, care being taken not to plant too deep. Roses may now be planted at any time. Manure the ground well, and if the natural soil be light give it also a good dressing of clay, and trench 2 or 3 feet deep; top-dress and double-dig all beds and borders which are cleared of plants, leaving the surface rough, which will expose it to the action of the winter frost. As the leaves are falling and being blown in all directions the lawns and walks will require extra attention to keep them clean and orderly. The broom and roller must be kept at work, so as to have the grounds as enjoyable as possible. The weather has been favourable for killing weeds, which should not be troublesome this autumn, for a better time for their extermination is seldom experienced at this season of the year.

This is, perhaps, the best time for propagating shrubby *Calceolarias*. They root well in light soil, with half an inch or so of sand on the surface; level and firm with the back of a spade, filling the boxes or frames to within 8 or 9 inches of the glass. After the cuttings are all in they will be the better for a slight watering to settle the soil, and for some days will require to be shaded and the lights kept close. Protect from frost in sharp weather. After the cuttings are rooted give air on every favourable opportunity. *T. Blair, Shrubland Park.*

FRUIT HOUSES.

PEACHES AND NECTARINES.—In the foremost division in this department the leaves of the trees will have completed their functions and dropped off. Should, however, any of these still hang on they should be removed by hand, so that the usual requirements which are annually and absolutely necessary in the way of cleaning be proceeded with, and a riddance of insect pests, which are sure to be present in some degree and form of development, be effected. It is a customary practice with us to take the lights off the peacheries when the buds are tolerably well developed, and in the case of the early started trees it is usually done at about the middle of September, and these are replaced again towards the end of October and later on in the case of successional houses. Under any circumstances an abundant supply of air is highly essential during the dormant period. Pruning, which is a most important operation, should only be done by a practised hand, and still the manner of execution differs materially in some points. With many it is customary to shorten back the shoots considerably—a plan which we adopt in later houses, but in the case of early started trees we elect to retain, as far as practicable, the growths in their entirety, because, under the pressure of advanced forcing operations, the woodbuds sometimes do not break forth so regularly as is desirable, and, moreover, fruit is by these means sometimes secured which otherwise would have been defective from this cause, and, still further, if necessary, it gives the advantage of disbudding so as to meet circumstantial requirements. An intelligible indication in practice is observable with trees which are well studded with spurs, as such rarely fail, with proper attention, to give a good supply of ripe fruit, and therefore the formation of these on the trees should be encouraged in this way, as frequently indicated in this Calendar—by stopping the growths which are not required to run during the growing period. Set out the growths sufficiently to admit of those of the forthcoming season having ample space to develop themselves perfectly. If any trees be at all infested with the brown-scale, a common enemy to these subjects, the safest and most certain way of eradicating it is by separating it from the shoots by means of a short stiff-haired brush, after which apply a dressing of the ordinary composition, to which should be added some strong tobacco-water and a little Gishurst Compound. After the trees are retied to the trellis, remove all the loose materials about the borders and also any inert soil; for this substitute fresh material, at the same time do not neglect the opportunity to examine the state of the borders, as at this period the soil about the roots should contain plenty of moisture. As the leaves fall from the trees in later houses they should be collected and removed, and the ordinary requirements as indicated for early houses in like manner carried out. Where several peacheries exist a partial lifting of the roots

or shortening them back is almost sure to be required. This operation should not much longer be deferred, as the sooner it is carried out the better. *George T. Miles, Wycombe Abbey.*

HARDY FRUIT GARDEN.

The dry sunny weather with which we have of late been favoured has had a most beneficial effect on all fruit trees in ridding them of much crude watery matter, and assisting them greatly in the process of ripening their wood. In order to derive all the advantage from what little solar heat we are now likely to get, Peaches and Nectarines should be lightly brushed over with a new twiggy broom, so as to remove any leaves that hang loosely on and are of no further service in nourishing the buds. Although attaching the fullest importance to preserving the foliage of trees up to the latest period possible, still in the case of the above trained to walls, with the leaves depending over the branches in the way they do, and completely covering them up from the influence of sun and air, it is necessary to assist Nature in her work, the more so as the walls form a shelter from winds and frost that act as Nature's handmaids and strew the leaves when their season's work is done. The brushing, however, should be of the gentlest kind, and carried on from the base of the tree to the summit of the branches, and not in the reverse direction, as some of the buds would thereby be destroyed or injured and the leaves forcibly detached from their hold.

October is, or ought to be, to the intelligent fruit grower the busiest month of the whole year, as in it there is much to be done by way of trenching and preparing for planting, the season for which is now close at hand. In the case of large trees that simply have to be moved from one part of the garden to another to fill up gaps, the operation should be taken in hand forthwith, as from the short space of time the roots are exposed there need be no fear of their taking any harm, or that the bark of the branches will become contracted in the way it does when the wood is not thoroughly hard and ripe and they are long out of the ground in coming from a distance. By transplanting thus early they get to work at once, and make considerable progress before the cold winter rains set in, and are therefore ready to respond to the call made on them when the time arrives for them to push forth their buds. During the process of filling in, the roots should be carefully spread out at different levels, according to the positions they previously occupied in the border, and as soon as fairly covered should receive a good watering applied with some force to wash the soil well in around them. After standing a few hours to subside the soil will be in a fit condition to receive the remainder, over which a thick mulching of hal rotten manure should be scattered to keep out frost and maintain a uniform condition in regard to heat and moisture.

Not only is the present time the most favourable for transplanting all kinds of fruit trees, but it is equally so for overhauling and renovating old borders, and for carrying out any root-pruning that may be necessary, an operation that is often productive of most satisfactory results, and one that does not receive the attention it ought. Those who have seen trees in market gardens cannot fail to have been struck with their fruitfulness—a condition brought about not so much by any treatment the tops are subjected to as by the constant root-pruning they receive under a system of deep cultivation. Unfruitfulness is generally brought about through the roots, when left to themselves, penetrating deep down into soil that is cold and wet or otherwise unsuitable, and from having a deficiency of fibre, the effect of which is at once seen in the strong sappy shoots they form, and in the absence of flower-buds. If these deep-seated roots are severed and brought nearer the surface, the feeders are increased a hundredfold and this tendency to woolly growth checked in a very simple and easy manner and without going to much labour. In the case of large trees, it is best to operate on one side only and leave the other till next autumn, as then there will be no risk of endangering their health, which there might be were the whole of the roots severed at once. For old decrepid trees or such as have got into a weak unsatisfactory state, it is surprising what a little fresh soil will do by way of bringing them round, especially if fresh cut turf is used without any admixture whatever. I have some now that have been entirely regenerated in this way that had suffered from having leaf-soil dug into the borders. The necessity of cropping these often leads to undecomposed vegetable matter being dug in, and which is in dry seasons very inimical to healthy root action, and its use should be avoided as much as possible. *J. Sheppard, Woolverstone.*

A SENSE OF PROPERTY.—Botanical old Gent (in the Brighton Gardens): "Can you tell me, my good man, if this plant belongs to the 'Arbutus' family?" Gardener (curtly): "No, sir, it don't. It belongs to the Corporation!" *Punch.*

THE
Gardeners' Chronicle.

SATURDAY, OCTOBER 20, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, Oct. 22—Sale of Dutch Bulbs, at Stevens' Rooms.
WEDNESDAY, Oct. 24 { Sale of Stove and Greenhouse Plants and
Dutch Bulbs, at Stevens' Rooms.
SATURDAY, Oct. 27—Sale of Dutch Bulbs, at Stevens' Rooms.

MR. SMITH'S paper on a FOSSIL FUNGUS, which we print in another column, together with illustrative figures, will undoubtedly excite much interest, and cause, probably, a great deal of speculation. *Lepidodendron* is a genus of trees which abounded in this country in the so-called Carboniferous epoch untold ages before red sandstone or oolite, chalk, or drift were deposited—when Tree Ferns spread their fronds over Yorkshire dales, and big Cycads and towering Conifers kept them company. The *Lepidodendron* itself may be said to have been a gigantic *Lycopodium*. The spores and fruits which have been found in association with them prove this. The mode of growth and the internal structure further substantiate the proof.

The climate and general conditions under which plants grew here in those times must have been considerably different to what obtain now, though probably less so than was at one time imagined. Then, as now, fungi played their appointed functions of preying upon decaying tissues; then, as now, their spawn tubes penetrated wherever suitable food was presented to them; then, as now, they increased and multiplied. All this is abundantly proved by the fungus which forms the subject of Mr. SMITH'S illustration. Several years since Mr. CARRUTHERS, our leading authority on all that pertains to fossil plants, detected similar growths and found the mycelial or spawn threads of a fungus among the tissues of a fossil Fern allied to our *Osmunda*. The fungus was so like the *Peronospora* that Mr. CARRUTHERS classed it with that genus. But the fungus threads on the *Osmundites* were mere babies compared to those which have formed the subject of Mr. SMITH'S observations. *Osmundites* grew in the muddy shores of the Thames in Eocene times, that is after the chalk hills were laid down. The time that must have elapsed between the deposit of the Coal Measure rocks and those of the London Clay period is so vast that the human mind can form no adequate idea of it, and yet whether it be *Peronospora*, whether it be *Pythium*, whatever its lineage in fact, the truth remains that in those two inconceivably remote periods a fungus closely allied to that causing the Potato disease of the present time existed. How insignificant appear man's works and their duration by the side of this lowly fungus. MOSES may have set eyes on Cleopatra's Needle, now it is to be hoped, after its abandonment in the Bay of Biscay, on its way to our shores, but what is the interval that separates our times from those of the Pharaohs in comparison with that which separates us from the time when tropical trees lined the banks of the Thames, and, still more remote, when our coal deposits took their origin from the overthrow of primeval forests? The fixity and constancy of so simple a form will at once attract attention, but this may readily be explained by the circumstance that so long as the plant was in harmony with the conditions under which it lived, so long would it live and multiply. As to the conditions, we know that many plants, especially among the more lowly organised ones, can make themselves at home under widely different conditions. Ferns, as Mr. CARRUTHERS has shown us, formed starch in their tissues in

Eocene times as now. The structure and appearance of the fossil plants of all epochs show that the essential processes of life were carried on then just as they are now—ceaseless change, unvarying constancy side by side.

Tempting as the subject may be, we cannot enter into the many speculations which this fossil *Peronospora* is calculated to excite. The adherent of the view of one original creation from which all living organisms are the direct descendants, will find his views strengthened by this tiny fragment of Palæozoic fungus. On the other hand, the evolutionist who adheres to the view that Creative Wisdom and Creative Power, so far from having been exerted once for all, have been exercised throughout all time and are still in operation will not find the fungus irreconcilable with his views. But these are questions into which we cannot here enter. One word, to conclude, will bring us back to the region of daily practice. When, in 1847, the Potato disease first appeared, the notion among the general public was that it was a new disease. When *Diphtheria* first began to be talked of as distinct from croup and scarlet fever, it was called a new disease. When a naturalist finds a plant or an animal previously unknown to him and science, he calls it in a conventional sense a new species, but Mr. SMITH'S fossil *Peronospora* is one more illustration that there is nothing new under the sun.

— WE regret that, on account of a delay wholly unavoidable on our parts, we are obliged to postpone the issue of the COLOURED PLATE of "True and False Mushrooms," announced to be presented to our readers with the present number.

— As a further contribution to the history of *CASIMIROA EDULIS*, figured in our last issue, the following description, sent with some seeds of the plant to the Kew Museum by Mr. SUTTON HAYES some years since, may be worth recording. The fruit is described as being known throughout San Salvador, Guatemala, and probably also in Honduras, under the name of *Matasano*. It grows to the size of a large Apple, and was indeed mistaken for an Apple the first time it was seen by Mr. SUTTON HAYES; this was near San Vicente in San Salvador. The taste is said to have a strong flavour of turpentine, which renders it very disagreeable to those unaccustomed to its use. The fruits are found for seven or eight months of the year in great abundance in nearly all the market-places throughout the above countries, and appear to form a large part of the food of the natives and other miserable people. The better classes seldom use them. The fruit in the higher parts of the country does not often perfect more than two or three seeds, and has less of the Terebinthine taste; that of the hottest localities is very large, generally with its five parts well and fully developed. Mr. HAYES remarks that it is strange that a fruit so much eaten by so many people should be so little known, even the most intelligent people, he says, in the countries where it grows seem to know nothing more about it than that it is very common in the market-places a great part of the year.

— The best ASTERS now in flower in the herbaceous ground at Kew are *A. longifolius*, *A. multiflorus*, *A. Chapmanni*, *A. turbinellus*, *A. lævis*, and *A. dumosus*. Among other noteworthy herbaceous plants in flower are *Stachys arenaria*, with pretty pink spikes reaching to less than a foot; *Alonsoa acutifolia*, bearing a number of rich orange flowers; *Lithospermum orientale*, clear yellow; *Convolvulus mauritanicus*, still with blue flowers in profusion; *Erica Watsoni*, *Senecio elegans*, a useful annual, with "double" flowers in several colours; the so-called green-flowered *Dahlia* (from the leafy scales of the receptacle); *Diplopappus rigidus*, with Aster-like flower-heads, in foliage much resembling a Heath; *Sedum spurium*, *Erodium Maniscae*, *Gaura Lindheimeri*, *Loasa lateritia*, and *Schizostylis coccinea*. At the rockwork are *Zauschneria californica*, *Lithospermum prostratum*, *Polygonum capitatum*, *P. Brunonis*, *Allium pulchellum*, and others less attractive in point of beauty.

— Our contemporary, the *Gardeners' Magazine*, takes us to task for having, in a leading article on the INTERNATIONAL POTATO EXHIBITION, misquoted an opinion previously given in that journal as to the proper size of exhibition tubers. We have no intention to shelter ourselves behind the somewhat vague expression "elsewhere suggested," as we admit at once the source of the quotation. Its appearance in an editorial, presumably penned by such an accepted authority on all that relates to the Potato, was our only reason for giving it special prominence. It was not said by our contemporary that 10 ounces in weight was a fair average size for an exhibition Potato, but that "10 ounces in weight should be the maximum size;" but as no mention of any minimum size was made, and therefore no guide offered as to what should be esteemed to be the "fair average," we concluded (as, perchance, did many more readers of the sentence) that 10 ounces was esteemed a fair exhibition weight, otherwise that weight would not have been so prominently mentioned. However, it is gratifying to find that our unfortunately misguided remarks have elicited such a definite expression of opinion from our contemporary, who tells us that he looks upon the 10-ounce average proposal as a "dreadful thing;" and we may henceforth confidently reckon upon his support to our previously expressed opinion, that tubers weighing three to the pound were of a fitting size to put upon the exhibition table, and a useful and profitable size for ordinary cooking purposes.

— A nurseryman in the North of England writes:—"Owing to the wet summer VIOLAS are to be very popular in gardens in the North. Pelargoniums have this season been a miserable failure." This remark applies to other bedding plants also. But *Viola* have been just the reverse of this, for they have flowered freely and continuously. They may be said to have saved the floral credit of many a flower-garden, and the continuous soaking rains which washed out the life and gaiety of Pelargoniums appears to lend a new lustre to the *Violas*.

— We learn from the *Daily News* that one GILES COLLINS, a labourer, in Wells, was fined 5s. on Tuesday last for keeping a live COLORADO BEETLE in his house. Who was the detective who identified the insect?

— A flowering shoot of the beautiful and interesting violet and white-flowered *SALVIA LEUCANTHA* has been sent us by B. PIFFARD, Esq., Hill House, Hemel Hempstead, Herts. Mr. PIFFARD brought the plant last year from the Botanic Garden at Draguignan, and describes it as a large, bushy, free-growing plant, and easily propagated. Our correspondent will send cuttings to any one who may desire to possess it, if they will apply before it is cut off by the frost.

— We hear sad accounts of the destructive effects of the gale which swept over the country early on Monday morning last, and which appears to have been the most severe which has been experienced during the last two years. According to the report issued from the Royal Observatory, Greenwich, the wind attained its greatest force at a quarter past two o'clock in the morning, when a pressure of 23 lb. on the square foot was registered, the direction of the gale being, until nine o'clock, S.S.W., S., and S.W.; afterwards, W., S.W., and W. So violent was the storm that the communication which is established for meteorological purposes with the Meteorological Office and the various ports on the south and western coasts was entirely interrupted. Trees seem especially to have suffered severely; and perhaps the most noteworthy case that has come under our notice is the uprooting of nearly twenty of the grand old Elm trees that have for so long been an ornament to Christ Church Walk at Oxford. Former Oxonians, and boating men especially, may also be interested to know that the famous Willow tree by Salter's Yard has also been laid low. A correspondent of the *Times*, writing from Budleigh Salterton, Devon, says:—

"A gale of terrific violence and unusual character passed over this part of Devon on Sunday night, culminating between the hours of 10 and 1 o'clock on Monday morning. Besides being of a force that none can remember its equal, it had all the characteristics of a genuine sirocco. The change over the appearance of

gardens and landscape on rising on Monday was of a magical nature, the former being hopelessly withered up, as though baked in an oven, while the latter has all the trees browned and dried up to a dirty brown paper appearance. Most houses have suffered, especially the thatched ones, and the boats were much damaged on the beach by the violence of the wind. This dry gale is a fit sequel to a summer of wonderful dryness here, there having been only twenty-seven days on which rain exceeding 3-100ths of an inch fell in the last 137, viz., from the beginning of June. Unfortunately, however, the corn harvest-time was wet."

The *Tuoro* correspondent of the same journal states that Saltash suffered severely, and Dr. Row's vineery, "said to be the largest in England," was entirely destroyed.

— We regret to state that during the violent hurricane which swept over Bristol and the west of England on Sunday evening last, very heavy loss was sustained by Messrs. MAULE & SONS, nurserymen, at their Stapleton Road Nurseries. The destruction of property all over the city was immense, but of all the sufferers Messrs. MAULE are the largest. Three large houses were utterly destroyed; one of these contained a large and noted collection of Orchids, another the finest collection of tree and other Ferns in the neighbourhood, whilst the third was their large vineery—the whole being found in one confused mass on Monday morning. Other houses and pits are much damaged, and it is calculated that the aggregate damage amounts to nearly £3000.

— CLEOPATRA'S NEEDLE on its way to our shores had to be cut adrift in the Bay of Biscay, not before five lives had unfortunately been sacrificed, but according to the latest telegrams, received as these lines are passing through the press, has been recovered and may still furnish material for the battle of the sites, if it survive that of the elements.

— We have received from Mr. McLEAN, gardener to Viscount HOLMESDALE, Linton Park, Maidstone, a flowering specimen of that singularly interesting botanical curiosity, *COLLETIA CRUCIATA*, or *C. BICTONENSIS*, the name by which it is better known. The plant is not often met with, but on account of its horny Ruscus-like habit and small bell-shaped flower, together with its perfectly hardy constitution, it should be planted in mixed collections more freely. Mr. McLEAN also sent a branch, bearing fruit, of *Calletia horrida*, which it will be remembered the late Mr. JAMES BARNES, of Bicton, believed to be the parent of the first named.

— We note in the last issue of the *Irish Farmers' Gazette* a lengthy report of the recent International Potato show, taken from the columns of *Bell's Messenger*, and, according to the honourable practice of our Irish contemporary, duly credited to that Journal. We also note that, with the exception of the first and four last paragraphs, the report is the same as that which appeared in the *Gardeners' Chronicle* of October 6.

— On the morning of Friday, the 12th inst., INVERARY CASTLE, the seat of the Duke of ARGYLL, and one of the most princely residences in Scotland, was partially destroyed by fire, and many thousands of pounds will have to be expended before the splendid edifice is restored to its former pitch of elegance, while it is to be regretted that many precious heirlooms are lost for ever. The fire broke out shortly before 5 A.M. at the top of the great central tower, which, with its Gothic casemates, lights the interior of the building; and so sudden was the alarm that all the noble ladies of the family, including the Princess LOUISE, were hurried into the open air barefooted and bareheaded in their dressing-gowns, with a rug thrown hastily about them. Fortunately the storm of rain and hail had spent its fury, and the ladies were speedily conveyed to the Argyll Arms Hotel by the Duke and his son, the Marquis of LORNE. An account of Inverary will be found in our columns, 1876, pp. 742, 777, 836.

— We understand that the *Villa Gardner* is in future to be conducted by Mr. WILLIAM EARLEY, of Valentines.

— The SHROPSHIRE DAMSON is said to be quite popular in Central and Southern Ohio, and, according to the *American Gardeners' Monthly*, there are

few Plams but Damsons to be seen in the Cincinnati markets, but these are abundant. Our contemporary remarks that this variety is "said to be in some respects superior to the common Damson." With us it has larger and more distinctly oval-shaped fruit than the common Damson, but is not so prolific. It is, however, the best of the two in all other respects.

— The BOROUGH OF HACKNEY CHRYSANTHEMUM SOCIETY, finding its former place of exhibition—the Town Hall, Hackney—too small for its requirements, have decided to hold its thirty-first annual show on November 20 and 21, at the Royal Aquarium, Westminster.

— On Tuesday last Mr. ROBERT FOULIS, gardener, forester, and estate overseer, at Fordel, Fifeshire, was entertained by a number of his friends at a dinner given in his honour at the Albert Hotel, Edinburgh, and presented with a gold watch and a purse of sovereigns, on the occasion of his having completed his fiftieth year in the service of G. W. M. HENDERSON, Esq. He was also presented with a handsome gold brooch for his wife. Bailie METHVEN occupied the chair, and Mr. DUNN, of the Dalkeith Palace Gardens, was croupier. The Chairman in proposing the health of Mr. FOULIS said, they had met on a very rare occasion indeed, for it was seldom that any one was found who had served for fifty years in one place as their friend had done, and with so much honour to himself. He had been nominally a gardener, and connected more especially with horticulture, but he had not confined himself to that branch of science alone. He had taken a deep interest in arboriculture, and had left his mark on the Fordel estate, which was noted throughout Scotland, and he might say in Great Britain, for all kinds of hardy plants. He had also taken a deep interest in geology, and had done much to communicate the knowledge he had acquired to younger men. He first became acquainted with Mr. FOULIS in 1835, and since that time he had always had a kindly feeling towards him. He had great pleasure in making the presentations to Mr. FOULIS, and hoped that he might long be spared to enjoy his retirement. Mr. FOULIS, when returning thanks, said it was gratifying to him to think that, after having lived amongst friends for fifty years, at the end of that period he was esteemed and respected by them. He felt that the merit attached to the position in which he was now placed was principally due to Mr. HENDERSON, who had proved a most excellent, kind, and indulgent employer, and one who had done a great deal to improve his estate. Although he had been a long time at Fordel, he had not attained to the length of service of his predecessor, who was gardener and forester there for sixty-three years, making 113 years in all between them.

— Now that the PEA SEASON is nearly over, many persons will be glad to know that an excellent substitute for use in soup may be found in the young tender tops, which may be had all through the winter by sowing a few pans or boxes at short intervals. The Peas should be sown in light, loose soil, and as soon as they show through be placed in narrow pits or frames near the glass, where they can get plenty of light to impart the requisite colour and flavour. Choice garden Peas are too dear and scarce to use for the purpose, but the field kinds will do almost equally well, and may be had at such a price that any one having the convenience of growing a few need not be debarred from enjoying soup almost as delicious as any that can be made in the summer. The canning process, so successful in the case of meats, appears a failure with vegetables, especially green Peas, the skins of which are hardened thereby, and the fleshy part done to a pulp, while their wholesomeness as an article of food is questionable, whereas there can be no doubt as to the nutritive properties of the young green tops, which are tender and succulent, and very digestible. The sowings may be made thick, so that little room need be occupied at any time; but as the germinating power of Peas is at a low ebb at this season, especially in the case of old seed, very careful watering is necessary, or they will be found to rot off.

— A correspondent writing with reference to "the OPOPODOLI or Duck's-mouth or Masamo," referred to by Professor REICHENBACH at p. 424, remarks that if he were not afraid of exposing his ignorance, he would ask who, or what, or which they

are? The answer is that these are the native indigenous names of *Cattleya (violacea) superba*! How much better vernacular names are than those crack-jaw words which botanists make!

— The charming *PRIMULA MUNROI*, singularly distinct as a species from most others of the large family of Primulaceae, is seldom met with in collections, and is too of ten pronounced niffy and impracticable. Perhaps this defect may have arisen from too much care and attention, too much coddling, or it may be that the original plants were deficient in that robustness and strength that have developed in some seedling forms. That these are strong and robust, and can rough it with any others of the family, we have had ample evidence this season; usually producing flowers of small size and of a rosy white hue, these seedling plants have large pure white flowers that might well be mistaken for those of *P. nivalis*, which they closely resemble. *Primula Munroi* has foliage not unlike a large form of *Sorrel*, throws its blooms up in a truss upon a stem of a few inches in height, and is so distinct that it ought to be found in every collection of hardy Primulas.

— A cursory examination of HARDY FRUIT TREES shows that the bloom-buds for next year are plumping up in great abundance, the recent spell of dry and comparatively warm weather greatly assisting in their development and in ripening the wood. Whatever may be the outcome of next season's bloom, there is no doubt but that it will be exceedingly abundant. It is, therefore, well just now to observe to what extent the growth on the trees generally bears evidence of maturity, or otherwise, for should another failure of crop result, we shall then be in a better position to judge whether that failure is due to possible spring frosts or to unripened wood. Perhaps it may not be out of place to caution growers that it will hardly be wise to inflict too great a check upon trees that have borne little fruit for two years, and therefore have produced a robust growth, by pruning hard, as it inevitably results in the reproduction of more barren wood. A moderate thinning is the most useful service to be rendered to hardy fruit trees this ensuing winter.

— To those who have to meet heavy demands for cut flowers—and their name is legion—we can strongly recommend a dwarf race of early flowering BEDDING CHRYSANTHEMUMS, which are making their way into the nurserymen's lists. Mr. PARKER, of Tooting, has been working at them for some time, and has got together a very choice collection, which we saw when in bloom. They prove to be fine border flowers, having a low bushy habit, are lavish in their production of flowers, come into bloom about June, and continue in blossom until frost puts an end to their beauty in autumn. If propagated by cuttings in spring, and grown on under liberal treatment, they make sturdy plants about 15 inches high, and some of the sorts about the same through— invaluable plants for cutting from, and, if grown in quantities in pots, would prove very serviceable substitutes for failures in the bedding-out. A good dozen to begin with will be found in the following sorts, all of which are of the dwarfest and earliest blooming types, and give a good variety of colours:—Delphine Caboché, Illustration, Cassy, Frederick Pell, Jardin des Plantes, in three varieties, pink and white, yellow, and white respectively; Madame Pecout, in two varieties, light and dark rose; Nanum, Scarlet Gem, and Precocity.

— The *Journal of the Central Horticultural Society of France* tells us that the name MAY DUKE, as applied to the Cherry, should properly be written My Duck!—that having been the original spelling of the name.

— Cut spikes of *GLADIOLUS RAMOSUS*, VILLE DE MARSEILLES, are now reaching London from Jersey. The flowers are pure white, with a rosy purple flame on the petals, and it is exceedingly pretty and distinct. It appears like a form that it would be advisable to cultivate in pots in this country, to prevent the delicate beauty of the flowers from being injured by vicissitudes of weather. It is an early-flowering form.

— *COLCHICUM SPECIOSUM* is now blooming finely in the bulb grounds of Messrs. BARR & SUGDEN,

at Tooting. It is the deepest coloured of all the Colchicums, the flowers large, stout, and well formed. A variety of *C. byzantinum* named *longipetalum* is also a desirable form, with much distinctness of character.

— A new dwarf LARKSPUR, which originated with Messrs. F. SANDER & Co., seed growers, St. Albans, promises to take a foremost rank among the new plants of the year. It has been somewhat inappropriately named EARL OF VERULAM, instead of receiving a designation which expresses its exceedingly dwarf and compact character. It grows to a height of some 4 or 5 inches, the compact foliage being in the form of a ball, and it throws up several spikes of flower from each plant, the spikes being dense, and the flowers of a rich ultramarine-blue on the guard petals; the central florets being violet-purple. It is continuous in bloom also if the decaying spikes be removed, blooming from July till October. It is a selection from some dwarf-growing form. It is recommended that the seed be sown where the plants are to flower, and if they be thinned out so as to stand some 8 inches or so apart the plants will fill out and

flowering Tritonias, and others, may be successfully grown and bloomed in this way. It is not wise to attempt to force these hardy bulbs into flower; they should be left to the promptings of Nature in a suitable temperature. What enjoyment can be got out of a cold house in early spring and summer suitable for the culture of such interesting things as those just alluded to! A selection of *Ixias* well suited for cultivation in pots will be found in *Aurora*, *Bucephalus*, *crateroides*, *Diana*, *Golden Drop*, *hybrida longiflora*, *maculosa*, *magnifica*, *Pallas*, *Plantus*, *Titus*, and *viridiflora*.

— Is it incorrect for a gold-laced POLYANTHUS to be represented as having the pip, or individual flower, divided into six segments? asks a correspondent. In looking through some of the old floricultural works containing coloured illustrations of florists' flowers the Polyanthus is represented as having, in some instances, five, and in others six segments to the pip. In the edition of MADDOCKS' *Florists' Directory*, published in 1792, a description of the properties of a fine Polyanthus is given, and it is set forth:—"The pips

with more than five segments. Looking at the matter from Nature's own point of view, five is the correct number.

— We recommend to the notice of our readers a little pamphlet which has just reached us, entitled HYDRO-INCUBATION, by means of which all kinds of poultry and game eggs may be inexpensively hatched and successfully reared all the year round (Christy & Co., Fenchurch Street). Villa gardeners and gardeners generally are so often interested in poultry, that we strongly commend this pamphlet to their notice, feeling assured that they will thank us for so doing. The subject-matter of the pamphlet is sufficiently indicated by its title.

— Some time ago we had the pleasure of announcing the honours received by Dr. H. R. GEPPERT, Director of the Botanic Garden at Breslau, on reaching his fiftieth anniversary of taking the degree of Doctor of Philosophy. On completing his hundredth course of lectures at the university last summer he was heartily congratulated and presented with a magnificent

FIG. 97.—A FOSSIL FUNGUS (*PERONOSPORITES ANTIQUARIUS*), WITH ITS MYCELIUM, GROWING AMID THE VASCULAR BUNDLES OF A *LEPIDODENDRON* FROM THE COAL MEASURES. (ENLARGED 250 DIAM.)

form a continuous line or mass. The examples of this charming Larkspur which we have seen were of such a character as to lead us to predict for it considerable popularity. The past summer has brought some fine additions to the class of hardy annuals.

— Now is the time for potting or planting out in beds the beautiful forms of *IXIAS* which Messrs. HOOPER & Co. and others are in the habit of exhibiting at one or more of the London exhibitions. They are not difficult to cultivate, and it is just possible that more failures result from what may be termed "coddling" the plants than from any other cause. They can be successfully grown and bloomed in pots in a soil made up of light loam, leaf-mould, and a good proportion of rough sand. The pots require to be well drained. The best time to pot is early in November, and any sized pot may be used, provided there is plenty of drainage at the bottom. When potted, they may be placed in a cold frame, or any such suitable place, and kept rather dry till the bulbs break into growth. Some water may then be given, to hasten development. When the flower-stems begin to appear the pots may be placed on the shady side of the greenhouse to flower. *Babianas*, *Cyclothrax*, *Sparaxis*, some of the pretty early-

should be large, quite flat, and as round as may be consistent with their peculiar beautiful figure, which is circular, excepting those small indentures between each division of the limbs, which divide it into five or six heart-like segments." The diagram of a Polyanthus bloom given by MADDOCKS has but five segments. Thirty years later, in an edition of THOMAS HOGG'S *Treatise on Florists' Flowers*, published in 1822, there was published a coloured illustration of a Polyanthus, and the flowers appeared with six segments each. Other illustrations given in various floricultural serials about the same time had in some cases five in others six segments to the flowers. GLENNY, in giving the properties of the Polyanthus, states distinctly:—"The single pip, or flower, should be divided in six places, forming six apparent flower-leaves, each of which should be indented in the centre to make it a kind of heart-shaped end; but the divisions must not reach the yellow eye." Thus the testimony of leading florists, who, it may be reasonably supposed, knew perfectly well what they were writing about, favours the idea that experience and personal observation have both pronounced in favour of Polyanthus blooms with six segments. But this has been questioned as a matter of fact by some who assert they have grown the Polyanthus for years, and never seen a flower

album of photographic views, and portraits of colleagues and former and present pupils. The album was bound in velvet and embellished with massive silver work in the Renaissance style. A wreath of Oak and Laurel leaves in beaten silver encircles the arms of the University of Breslau. The album contained no fewer than 554 portraits. Dr. COHN, as the oldest pupil on the committee, made an eloquent speech on the merits of the recipient.

— Mr. WOODROW, the superintendent of the botanical gardens at Gunesh Khind, Poona, has published a list of the DRUG-YIELDING PLANTS cultivated in the garden. The list includes about one hundred different plants, with their popular and technical names. The demand for many drugs being very slight, and not of a steady nature, it is often difficult to procure them fresh in the markets; and this list has been compiled with a view to such as are grown in the botanical gardens being utilised by the public.

— To the St. John's Worts already in cultivation will shortly have to be added a perfect gem in the rare *Hypericum acaule*, which produces its small golden-yellow blossoms in long dense spikes. Mr. PARKER has the only plants that we have seen.

A FOSSIL PERONOSPORA.*

(PERONOSPORITES ANTIQUARIUS, W. SM.)

THE fungus preserved in a fossil condition, and belonging to the Palæozoic age, came under my notice in the following manner:—Mr. William Carruthers, F.R.S., keeper of the Botanical Department of the British Museum, first observed this or a similar parasite some years ago in a slide belonging to the Museum collection prepared to show the nature of the vascular axis of a *Lepidodendron*. By the permission of Mr. Carruthers I have examined this original slide, which contains mycelium and oogonia; and I believe the fungus to be the same with the one now under description, although far less perfect, and without zoospores. The newer slide, part of which is now illustrated, enlarged, in fig. 97, 250 diameters from the original, was lent to Mr. Carruthers a few months ago by Mr. J. T. Young, F.G.S. Shortly after this

been detected upon any fossil mycelium. Mr. Carruthers has, however, directed attention to the wonderful fact of the cellular tissue of the *Osmundites*, the starch granules within the cells, and the very walls of the mycelium itself being perfectly intact, in the sense of the original forms being exactly reproduced to their minutest details by a deposit of inconceivably fine silica.

I believe that the fungus I have named *Peronosporites antiquarius*, in the scalariform axis of the stem of a *Lepidodendron* from the Coal Measures, has up to the present time only been examined in a somewhat slight manner, and has never been searchingly looked into. No description, except that of a *Mucor*, also from the Coal Measures, has hitherto been published of any well defined fungus belonging to the Palæozoic series of rocks. It is, however, possible that a paper in the *Annals and Magazine of Natural History*, 4th series, vol. iv., 1869, p. 221, and tabb. ix. and x., describes

zoosporangia (or oogonia), as seen within the vascular axis of the *Lepidodendron*, is shown in fig. 97, enlarged 250 diameters. Beginning with the mycelium, a close examination of this shows that it is furnished with numerous joints or septa. If, therefore, any reliance is to be placed upon the modern distinguishing characters of the now living species of *Peronospora* and *Pythium*, as furnished by a septate or non-septate mycelium, then the fossil parasite belongs to *Peronospora*, and cannot belong to *Pythium* or any of the *Saprolegniæ*. The oogonia do not agree with those of *Cystopus*. Within many of the fossil oogonia of the group illustrated, the differentiation of the protoplasm into zoospores is clearly seen; but if any doubt could exist as to the exact nature of this differentiation, then other oogonia (or zoosporangia) on the same slide show the contained zoospores with a clearness not to be exceeded by any living specimen of the present time. One of the most perfect groups of these Palæozoic bladders containing the once mobile spores is shown in fig. 98, enlarged to 400 diameters, and the wonderful fact becomes manifest that the bladder is exactly the same in size and character with average oogonia of the present day, especially with the same organisms belonging to *Peronospora infestans*. The contained zoospores are, moreover, the same in form and dimensions with the zoospores of *Peronospora infestans* when measured to the ten-thousandth of an inch. For comparison an oogonium and group of free zoospores enlarged 400 diameters, and belonging to the fungus of the Potato disease, is illustrated in fig. 99. On examination it will be seen that the organisms are apparently identical. The average number of zoospores in each oogonium is also the same, viz., seven or eight. The aerial condition of the fungus has not yet been observed.

FIG. 98.—THE FRUIT OF A FOSSIL FUNGUS (*PERONOSPORITES ANTIQUARIUS*) CONTAINING ZOOSPORES *IN SITU* AS SEEN AMONGST THE SCALARIFORM VESSELS OF A *LEPIDODENDRON* FROM THE COAL MEASURES. (ENLARGED 400 DIAM.)

FIG. 99.—FRUIT OF THE POTATO FUNGUS (*PERONOSPORA INFESTANS*), FROM THE TUBER OF A POTATO, TO SHOW UNIFORMITY IN SIZE WITH THE FOSSIL FUNGUS. (ENLARGED 400 DIAM.)

Several years ago Mr. Carruthers pointed out the extraordinary and exact agreement in form and size of the macrospores and microspores in the Palæozoic *Lepidodendron*, as found in the 'genus *Triplosporites*', with recent species of *Selaginella*, and the occurrence of microspores only in the Palæozoic genus of *Lepidodendron* named *Flemingites*, in exact agreement with the habit of the members of the genus *Lycopodium* of the present time. The agreement in habit, form, and size of the Palæozoic parasite with the parasites of to-day adds an additional and important item to Mr. Carruthers' valuable observations.

In *Peronosporites antiquarius* we then probably have one of the simple primordial plants of the great family of fungi. The *Peronosporæ* are closely allied to the *Algæ*—so closely, indeed, that De Bary says the species of the former may with reason be compared with the species of one group of the latter, named the *Saprolegniæ*; other botanists place the *Saprolegniæ* amongst true fungi. If *Peronospora* is, therefore, an *Alga* (and its extremely close relationship is doubted by none), we have in *Peronosporites antiquarius* a plant which, from its extreme antiquity, lends some favour to the views of Sachs and other evolutionists. These observers place the lower *Algæ* amongst the primeval plants from which fungi and all other cellular *Cryptogams* have branched. This position is hardly invalidated by the presence of the more highly organised vascular *Cryptogams* living at the same period of time with the primordial *Alga* or fungus, for although the vegetable kingdom may have now reached a generally much higher development throughout the world than in the Palæozoic age, yet this fact does not make the supposition unreasonable that the lowest forms of life may even now be springing from no-life—may be under the process of creation, or under the process of being evolved from still lower forms of life beyond the reach of our microscopes or comprehension. The lower forms of life of to-day are probably destined for development into

time Mr. Carruthers placed the section (with two others) in my hands for careful examination. The slides were seen when in the British Museum by Dr. Rostafinski, and this gentleman expressed his belief (from a hasty examination only) that the parasite in the vascular bundles belonged to the genus *Pythium*.

It may be stated here that not only was Mr. Carruthers the first to detect the fossil fungus now being described, but he was the first to observe and illustrate certain mycelial threads seen by him amongst the cells of a fossil Fern (*Osmunda*) from the lower Eocene strata of Herne Bay. The fossil Fern was named *Osmundites Dowkeri*, and the parasitic threads were referred by Mr. Carruthers to the genus *Peronospora*. Silicified mycelia have been known for some time; Mr. Darwin informs me that fungus threads in a fossil state were shown to him in silicified wood more than forty years ago by Mr. Robert Brown, a predecessor of Mr. Carruthers in the Department of Botany at the British Museum.

So far as I am aware no perfect fruit has hitherto

and illustrates a fungus of a somewhat similar nature with my *Peronosporites*. The paper in question is communicated by Messrs. Albany Hancock, F.L.S., and Thos. Atthey, and purports to describe five species of "*Archagaricon*" from the Cramlington black shale. The authors state that the fossil fungus has been found at Newsham and in other localities. They, however, describe "lenticular swellings" with a "reticulated surface," which I have never seen, and spore-like bodies within the mycelium, which is clearly an error of observation. The authors also refer their plant to *Sclerotium stipitatum*, and they say they can find no "important difference" to distinguish this latter plant from their coal fungi. Of course *Sclerotium* is not a fungus at all, but a mass of condensed mycelium, and the Cramlington plants do not resemble *Sclerotia*. Plate x. might pass for *Peronosporites* drawn by a bad draughtsman unacquainted with fungi, but as the descriptions are imperfect and do not give critical dimensions, no one can say what Messrs. Hancock and Atthey really had in view.

One of the most instructive groups of threads and fruit, or, more properly speaking, mycelia and

* A paper read by Worthington G. Smith, F.L.S., at the meeting of the Woolhope Club, Hereford, October 4, 1877.

diverse forms for future ages; but this is no reason why the well-spring itself should stop at its source, whatever that mysterious and unknown source may be.

The evolution of animals and plants is quite comparable with the ages of stone, bronze, and iron with reference to the different tribes of the human family. Because the stone age dates back to dim antiquity it does not follow that it has entirely vanished from off the face of the earth. When Britain was in the stone age the chipping of flints had given place elsewhere to the manufacture of instruments of bronze, and even now, when the age of iron and steel has been reached, many tribes of the human family still live in the age of stone. One state of things (without itself completely dying out) gradually gives rise to another. But throughout Nature it will be seen that in one way or other the old source, be it Palæozoic or Palæolithic, still exists at the same time with the objects of that source's highest development. It is clear that the law which called the Peronosporites into existence countless ages ago is in force now, and that this law produces the same results now as then. Whatever changes may have taken place in the external aspects of natural objects the fact clearly remains, that the great law which first called these objects into being has from the most remote ages remained perfectly unchanged.

Home Correspondence.

The Late Potato Show at the Aquarium.—I observe a note in the *Gardeners' Chronicle* with the above heading signed "A Committeeman," in which the writer complains of the treatment he received by the manager. After reading the note, I said to myself "Serve Mr. Committeeman right; surely the promoters could have found a more suitable place in which to hold the exhibition than the Westminster Aquarium;" but my main object in writing is to denounce a principle which seems to be encouraged by people who ought to know better and who one would think were capable of taking a broad view of the situation, and I cannot help thinking but that vanity lies at the root of the whole matter. Tulip, Auricula, Gooseberry, Potato and a host of other societies relating to horticulture are established, committees formed which have not got the means or organisation to carry out the work themselves, and therefore either go to the saloon at Westminster or to the one kept by Messrs. Bertram & Roberts at Muswell Hill and ask assistance at their hands, assistance which is given with the view that probably this Potato or Carnation society may bring some people together to drink some gin. I hold that it is an incongruous, degrading, and unwholly alliance, and one that all lovers of horticulture ought strenuously to oppose. And then we hear these said committeemen wondering how it is that the Royal Horticultural is not a success. I hold that one reason why the Society does not succeed is in consequence of the action taken by these little societies; if they would only throw in their influence with the parent society we should certainly have a stronger central one: but then Messrs. Brown, Jones, and Robinson would not be prominent individuals, and that being of more importance than the promotion of horticulture we find the present unhealthy state of things prevalent, and it is to be hoped that the next time the Potato, Carnation, or Rose Society seeks the support of gin and beer the "committeemen" may not only be hustled out but also their exhibits. Horticulture ought to have nothing to do either with the public-house or joint-stock companies. A. B. [Our correspondent expresses himself strongly, but in principle we entirely agree with him. Eds.]

Three Days' Shows and Saturday Terminations.—I wish to endorse every word that Mr. Coleman has written on this subject at p. 467, and by recording my own experience as an exhibitor at the shows be more particularly refers to, strengthen, if possible, his position by way of inducing the authorities to avoid three days' shows, and more especially Saturday night terminations to them. The Alexandra Palace show did not close till 8 P.M. on Saturday, at which hour the tables were densely surrounded with visitors, many of whom were eager to buy fruit, but many still more eager to beg it; and what with the hubbub and crush it was a sheer impossibility to pack up expeditiously with, as in my case, a view of catching a certain train. I however did succeed in catching the train leaving Paddington at 12 midnight, reaching Reading at 2.45 A.M., and, having then to drive 9 miles, reached home at 3.30 on Sunday morning. Now when it is remembered that I am only about 50 miles from the Alexandra Palace, it will be seen (and I hope by the authorities admitted and remedied) how inconvenient it is for such distant exhibitors as Messrs. Coleman, Bannerman, Goodacre,

and many others. The Crystal Palace show, closing as it did at 5 P.M., was somewhat better, but even in this case distant exhibitors could not get home the same evening. W. Wildsmith, *Hockfield*.

—I am very much pleased to see that Mr. Coleman has brought the subject of three days' shows, terminating on Saturday evenings, under your notice. I quite agree with him in all his remarks; and from the conversation which I had with a great number of the principal exhibitors at the Alexandra Palace show, I feel sure that, unless these kinds of shows be discontinued, exhibitors from a distance will not attend them, and then indeed they would cut a sorry figure in the future. I am of opinion that two days' shows are quite long enough at any time of the year, and that they should begin on any day other than Monday. There is one more subject which I should like to call the attention of secretaries to prior to the getting out of their schedules for next year, and that is, the objectionable practice of exhibitors selling their produce at the termination of the show, which is not only objectionable, but very much interferes with those who wish to pack up their fruit to take home. I think those who wish to sell their fruit should remove it from the premises, and not turn the exhibition into a sale-room. If you will kindly find me a space for these few lines in your next issue, and assist us in getting our grievance removed, you will not only confer a personal favour upon myself, but also confer a great boon upon all gardeners. W. G. *Praeger, Castle Gardens, Sherborne, Dorset*.

—There are very few exhibitors who do not feel more or less the great inconvenience and loss attending the present system of holding shows on the three last days of the week, and mostly extending the closing time till a late hour on the finishing Saturday night, making it almost impossible for exhibitors to remove their produce till the following Monday. This practice makes it most inconvenient to exhibitors one and all, and it is to be hoped that Mr. Coleman will receive every support in his courteous appeal to the promoters of our great shows: they will see at a glance the unnecessary inconveniences and expenses it involves, and sometimes the entire sacrifice of perishable exhibits. Employers generally object to long shows on account of the sad condition of tender exhibits when brought home—they are in nearly every case unfit for use. Committees are to be commended for their kind consideration of the working classes, but where there is a will there is a way, and I think the working classes could conveniently attend before the late hours on a Saturday, when it very often happens, unfortunately, that the visitors prove rather unruly and reckless. J. H. *Goodacre, Ebbwastan*.

New French Roses.—Referring to your remarks in last week's *Gardeners' Chronicle* about the annual issue of new French Roses I find that, although you have shown a considerable amount of knowledge of the merits of these Roses, I perceive, upon reference to the French catalogues, that your information, as far as regards numbers, is very incomplete. Instead of 165 varieties being offered during the last five years I find there are no less than 309, thus leaving 144 to be identified either as good, indifferent, or bad. Perhaps some of your Rose-growing readers can give us some account of the qualities of the 144 which you seem to have overlooked. S. X.

How to Keep Nuts.—I can strongly recommend the system that Mr. Ward advocates for keeping nuts. The plan I have adopted for some years is very similar, the difference being that I use no bricks, or salt to keep the nuts fresh. I gather the nuts on dry days, and having some 9 and 12-inch pots dry and clean, place a piece of slate over the drainage hole, fill the pots with nuts, and place another piece of slate over the top of pot, and bury them about 3 or 9 inches below the surface of the soil, placing a small stake to denote where the pot or pots are. We gathered our 1875 crop in the last week of September, and stored them away as above described; and I sent the last dishes of those nuts in for dessert (beautiful and plump) in the first week of November, 1875, and they were pronounced by my employer's guests as "excellent." The hot weather of July, 1875, did not affect them in the least, although they were on an open border in the kitchen garden, the ground being exposed to the sun from morn to eve. Jas. *Batters, Gr., Chilworth Manor, Romsey*.

Eucharis amazonica as a Cool Greenhouse Plant when in Flower.—It is seldom one sees this finest of all the white Lily-like plants in the cool greenhouse or indoor garden. Few plants, however, are better adapted for such positions. It bears the cold of common greenhouse treatment with impunity, and continues in flower for at least two months under such conditions. As soon as the flowers fade take the plant into the stove, or, better still, a close pit, with a bed of tan or leaves or other fermenting materials for bottom-heat. Plunge the plants in this hotbed and subject top and bottom to a bottom and surface tem-

perature of from 65° to 80°; water liberally with clear guano or soot-water or house sewage, and soon the plants will make fresh growth and produce another splendid crop of bloom. They may thus be gradually hardened off and planted again in cool quarters. These pressures and changes of temperature may be so managed as to command three or more crops of bloom in the season. Under a cool *régime* less water is needful and manure-water should be dispensed with. In fact, as a rule, all such stimulants should be banished from the conservatory and indoor garden, as the ordure of the mansion, even when used in a liquid form, is a very incongruous accompaniment to the sweet perfume of the flowers. By these sudden alternations of heat and cold these may be bloomed in 6 or 8-inch pots, and those small plants are among the most beautiful and useful of all for the decoration of the indoor garden, the filling of small vases in houses, &c. D. T. F.

The "Beauty of Glazenwood" Rose.—I see in the nurserymen's lists of Roses mention of "Porteous" Briar, or Beauty of Glazenwood, as a new Rose, or at least an old variety revived. May I give the history of this "revival"? In 1870 I was at Meran in the Tyrol, and there I saw this Rose in bloom. I obtained two buds, sent them home in a letter, with their ends inserted into pieces of raw Potato to prevent escape of sap, to the gardener at Hedingham Castle. One of the buds took, and the Rose bloomed well on a south wall at Hedingham. I called the Rose "Meran," and as such it was known by our friends, so much so that we had the usual stamped zinc labels in use for it. Last autumn I saw in Messrs. Paul's list a new Tea Rose advertised as sent out by Mr. Woodthorpe, called the Beauty of Glazenwood! From the description I felt sure that it was our "Meran" Rose. It proved on inquiry to be that Rose, which had been propagated from a bud of the Rose first tried at Hedingham. I want to claim for it the name by which it ought to be known, "Meran." In its way it is singularly beautiful. *Severne Majestic, Drumlanrig Castle, Thornhill*. [The Floral Committee came to the conclusion that the so-called "Beauty of Glazenwood" and the old Fortune's Yellow Rose, were one and the same thing. Eds.]

Astilbe rivularis.—This fine plant resembles the Spiræas, and among the herbaceous kinds may be considered the emperor. Its enormous leaves resemble the fronds of some Tree Fern, or the foliage of some Smilax, but when it throws up its immense panicles of thickly-clustered creamy-white flowers, it is a most telling object. It is not fit for the herbaceous border, throwing out underground stems from 4 feet to 6 feet in length, which at the apex throw up masses of such foliage as no one would attempt to destroy. It would soon monopolise a whole garden, and such a garden would be a noble sight—quite a tropical jungle. It is just the plant for thin or neglected shrubberies, where it would fill all gaps and open spaces with foliage and flowers such as no shrub possesses. Where coach roads or drives pass through open groves or woods the plant would soon be naturalised; and would form thickets like the common Bracken, even in damp, swampy places, where the Bracken would not live. *Thomas Williams, Ormskirke*.

Arundo Donax.—The merits of this as a hardy ornamental plant to use in the sub-tropical garden or as a single specimen on lawns appear to be almost entirely overlooked, for excepting one or two places I do not remember to have met with it anywhere but here for many years past. We have it in the background of shrubbery borders and a strikingly ornamental object it is in such a position, relieving as it does the regularity of outlines that generally prevails more or less among such things as Aucubas, Hollies, Laurustinus, &c., that are generally used pretty freely when planting such places. Much glass-room and valuable time is occupied in raising tender subjects annually that perish with the first frost, while there are many that are equally as beautiful and more serviceable, inasmuch as they require no further care or attention when once they get a fair start, and this *Arundo* is one of the best. Planted in very small clumps a few years ago they are now bold masses, with stems from 9 to 12 feet high, that with their elegant drooping leaves wave to and fro by the slightest movement of the wind in the most graceful manner, this rendering them very attractive. For planting on small islands in lakes, or near the margin of the same, they are unsurpassed by any plant I know, excepting the hardier Bamboos, with which they associate well and form quite a distinctive feature in positions of that kind. It often occurs that the banks of artificial ponds are bare and formal-looking, when by arranging a few groups of such suitable plants as the above a natural look would at once be imparted that would improve as time wore on, and allowed Weeping Willows to get into size. The best time to plant in such situations is early in spring, just as they are starting

into growth, as then they emit fresh root with the young shoots they send up, and there is no risk of losing them as there would be if removed during the winter while in a dormant state. In planting the Arundo Donax near lakes, the best effect is produced by having the common Sedge next to it in the water, and the Arundo on the bank, so as to form a continuation of the same kind of vegetation; this will be the more striking from the great height the latter attains. Again, the Pampas-grass or Arundo conspicua, with their gracefully recurved leaves as a foreground, blend well with the elegantly arching Bamboos, the latter of which are not half as much appreciated or used in ornamental planting as their great worth for such purposes entitles them to. All the above do best in loose, moist soil, although they will thrive anywhere; but before planting the ground should be well broken up, and if stiff, have plenty of leaf-mould or peat and sand worked in to keep it open, so as to allow the roots to ramify freely. S. W.

Hydrangea paniculata grandiflora.—When on a recent visit to the nurseries of Messrs. Roger, McClelland & Co., Newry, Ireland, I saw some beds of this grand shrub flowering most luxuriantly, with many of the trusses of its pinkish white flowers measuring 12 inches long and 3 through at the base. In favourable spots this ought to be more generally cultivated, for it is well worthy the attention of those who require flowering shrubs at this season of the year. A. Outram.

Vine Mildew.—A correspondent states at page 304—"It is a somewhat remarkable fact that Vine mildew seldom displays itself on Vines grown in the open air." Likewise "we have lately seen in rural districts large quantities of Grapes produced on cottages, yet not a trace of mildew could be found." Thus, he concludes, the pest displays itself only on tender Vines under glass. But if he was in this locality he might see hardy Vines on the front of cottages affected by mildew as badly as those in hot-houses. In fact, how can it be otherwise when the fine dust or mildew spores are wafted about and root on plants suitable for their growth? Those who have studied this subject consider that such spores underlie the brown spots on Vine shoots of the current season, which open in spring, and give out clouds of invisible seed, and thus renew the pest with more or less vigour, according to the state of the atmosphere. That agrees also with the curious way other kinds of mildew, commonly called blights, are bred. I refrain from going into mildew cures, though I have tried some of them having high-sounding testimonials, which have given poor results, owing greatly to the mysterious growth of the parasite. For instance, a healthy Vine may be covered unseen with its spores till the visible mildew suddenly appears rooting on the skins of the berries, sickening to one who knows that the enemy can only be grappled with at the risk of spoiling a house of Grapes. Since the above was written, I have seen M. Bréhaut's account at p. 374 respecting "a badly mildewed crop of Grapes being cured by wiping the berries about once a-week for six weeks." I have tried the plan, but as he says truly, at the loss of bloom, because the wiped berries shine like black Cherries. Such a loss, however, is a gain, as the spores of mildew vegetate only on the waxy varnish which protects the foliage and fruit from injury; the same acts against mildew washes, causing them to drip off like water from a duck. Again, the fumes of sulphur can only be applied with great danger. Many have "burned their fingers" by such. Supposing otherwise, the berries turn rusty and crack—in fact, are more unsightly than when they are sponged with clean water, say only once, because mildew does not display itself after the bloom is gone. J. Wighton.

Evergreen for a Churchyard.—In a recent number of the *Gardeners' Chronicle* your correspondent "J. A. E. A." begs a suggestion of some small bright plant that would keep green all the winter, low and compact in habit, for placing on a memorial stone in a village churchyard. Would not some of our hardy Heaths be perfectly adapted to the purpose? By placing the Erica carnea close to the stone the branches would spread over it, and its rose-coloured blossoms in early spring and deep green foliage, invariably trim and neat throughout the year, would be always pleasing. If a larger plant was admissible the E. vagans, the Cornish Heath, in its white variety, would be very appropriate in the long enduring and perfect purity of its white blossoms, and the almost imperceptible disorder of their fall. O.

Phlox Drummondii grandiflora.—Phlox Drummondii has been a special favourite for many years, but is now eclipsed by a much larger variety, called splendens grandiflora, that is destined ere long to drive the old kind out of cultivation. Its name conveys an idea what the flowers are as compared with its prototype, and is really not an exaggeration,

as they are both splendid and grand, being exceedingly brilliant in colour and of large size, perfect in form and of great substance. The plant, too, has altogether a more vigorous habit, with stouter stems, and is less procumbent, and therefore better adapted for filling large beds or growing for cutting—a purpose for which it is particularly suitable, owing to its light appearance and the great length of time it lasts in water. Although looked on as an annual the Phlox Drummondii may be perpetuated by cuttings—and it is often worth while to do this when anything special occurs among a batch of seedlings. In order to winter them safely they should have a little heat, such as is afforded to fancy Pelargoniums or plants of that class, and be stood on light, airy shelves near the glass, where damp is not likely to affect them. From the free manner in which some that were sown late are now flowering, I am inclined to think that they would be most valuable to grow in pots for greenhouse decoration, to bloom at and after this time; or if sown now, or grown on from cuttings, to do so early in the spring—a season when they would be even more useful to blend with the pale flowers of Lily of the Valley, Spiræas, &c. As bedding plants, either in mixed or separate colours, they make a fine display, especially where they can have a rich, deep soil afforded them, and a slight mulching of old Mushroom dung or anything of that kind to keep the ground shaded. The present season has been particularly favourable for them, and while Pelargoniums and other plants outdoors have lost most of their flowers, Phlox Drummondii grandiflora is still as bright as ever, and looks likely to continue so till destroyed by the frost. J. S.

Dimensions of Trees in Banffshire.—At p. 435 you gave the circumference of the largest specimens of trees growing in Aberdeenshire, as found by Dr. Dickie in 1843. I don't know what may be the exact size of the largest trees to be found in Aberdeenshire at present, or what may be the increase in size of those referred to, if they be still standing; but from measurements which I have made of trees growing here, and which I contrast below with those furnished by Dr. Dickie, I am inclined to think that Banffshire, although further north, can boast of larger trees than Aberdeenshire. There is, I think, one thing at least remarkable about these trees—instead of being found in different localities and on soil specially suited to the different varieties, they are all growing within a radius of 300 yards round about Rothiemay House. The measurements were taken at a height of 4 feet above the ground:—

	In Aberdeenshire.		At Rothiemay House.	
Larch	Mar Lodge ..	10 ft. 1 in.	10 ft. 11 in.	0.
Silver Fir ..	Strichen ..	10 11	11 11	0.
Elm	Craibston ..	9 8	16 0	0.
Sycamore ..	Glenkindy ..	11 1	12 6	6
Gean	Edinglassie ..	7 6	8 3	3
Aspen	Invercauld ..	6 10	13 9	9
Horse Chestnut	Crathes ..	9 0	10 0	0
Lime	Aboyne ..	9 8	11 9	9

There is also within the same radius a Laburnum which measures 3 feet 8 inches 4 feet above ground, and a Wellingtonia gigantea measuring 4 feet 3 inches 2 feet above ground. Alex. Lawson, Gr. to W. J. Taylor, Esq., Rothiemay House, Banffshire, Oct. 13.

Seedling Begonias.—In Messrs. Roger, McClelland & Co.'s nurseries at Newry there is perhaps one of the finest collections of seedling Begonias to be seen. Some thousands of different sized plants are grown in perfection, and many of them are quite new in colour, as well as showing great improvements in habit. These for general decorative purposes cannot be excelled. Those who visited the Carlisle show in September will recollect the fine display of seedlings exhibited by this firm, many of which were worthy the attention of growers. Mr. Smith, the manager of these nurseries, and to whom the credit of raising many good varieties is due, has several planted out-of-doors, and on October 6, when I was there, they were in great perfection, far surpassing the beds of Pelargoniums close by, which is sufficient to convince one that in favourable climates these will prove very valuable for the decoration of our flower gardens in the autumn. A. Outram.

An Easy Method of Growing Grapes.—Few presents are more acceptable, nor often more useful than a nice bunch of Grapes, and to be able to grow such a luxury, to place such a delicacy on our own table, is something to be proud of; but the difficulties that stand in the way seem disheartening to a non-professional, when in reality they are easily overcome if right means are employed, and this can be accomplished by a comparatively inexpensive process, which I submit to your readers, as seen in the garden of H. Badcock, Esq., Broadlands, Taunton. In a corner of the kitchen garden, south aspect, stands an old forcing pit, with pigeonholes in the walls, such as

were used before hot-water made its horticultural mark. Behind this pit, against a wall, there is growing a Vine of the Bidwill's Seedling, which has on it a very heavy crop, but these cannot now ripen, the season has been so cold throughout. Branches have been detached from the outside on the wall and introduced into this pit, the shoots trained about 2 feet from the glass. The air is freely and continually passing through the perforated walls, and so giving a thorough ventilation, which seems to suit the Vines admirably, as they are free from mildew or insects, and are robustly vigorous and healthy. There is no heat given beyond that from the sun, no richly prepared Vine border, no bountiful and costly supply of phosphates and nitrates. The Vines are planted in the garden border, and there is now hanging thereon a capital crop of Grapes, well ripened, well coloured, and of good flavour, many of the bunches being 2 lb. in weight. Mr. Kimmins, the persevering and industrious gardener, with small trouble here secures a nice succession crop of Grapes, to save his later houses. The process is so simple, the result so certain and satisfactory, that many amateurs might find a corner in their garden where at a very small cost they might enjoy the pleasure of eating Grapes of their own growing. William Payne, Gr. to J. Marshall, Esq., Belmont, Taunton. [Bidwill's Seedling is generally very indifferent in flavour. EDS.]

Magnolia Campbelli.—There is growing in the garden of John Marshall, Esq., Belmont, Taunton, a plant of the above Magnolia. It is planted out in ordinary garden soil, improved by a mixture of sand and peat, eastern aspect, trained and nailed against a wall, situation moderately sheltered and shaded. It is growing most rapidly, making shoots 2½ to 3 feet long, with fine large foliage of a light green colour. I have never had the pleasure to see this variety in flower, and I am very anxious to know if any one has bloomed it in an open situation, such as above described. William Payne, Belmont.

Telegraph Cucumber.—I, too, like your correspondent, Mr. Rust, often wish that I could have the strength of mind to keep only to one variety of Cucumber and Melon, for as regards the latter, if I had done so, it would this year have saved me much disappointment and vexation, as in growing so many sorts they have got mixed from crossing, and are scarcely equal to those they originated from. The favourite here is the Sultan, a Melon much resembling the old Bramham Hall, very handsome, and of first-class quality, and I have cut matters short by throwing away all others, with the hope that I may depend on having a pure stock in future. As regards Cucumbers, I grow nothing else but Sion House or Lord Kenyon's for winter, and Telegraph for summer use, and none better can be had or desired. For crispness and flavour Lord Kenyon's is unsurpassed, and the standard in those respects of what a good Cucumber ought to be. J. S.

Gunnera scabra.—We cut to-day a spike of fruit of Gunnera scabra, weighing 10 lb.; length, including stem, 2 feet 3½ inches, very evenly grown, and the pips quite orange-yellow. Is this above the ordinary size and weight? I may add, the plant is growing near water, and appears to be a gross feeder. A. S. Kemp. [This appears to have been a well-grown sample. EDS.]

Tuberous Begonias.—The statement that Begonia tubercules can be stored away dry out of the reach of frost to take their rest in winter, sheltered from its severity in an outhouse or on a greenhouse shelf, which Mr. T. Smith, of Newry, pronounces to be "all wrong," is not mine, but the late Van Houtte's; and, as I presume the aim of the *Gardeners' Chronicle* to be not so much to prove who amongst its correspondents is right and who is wrong, as to elicit what is right in gardening matters and what is wrong, I hasten to express my belief that Mr. Smith's instructions to winter the tubercules in pots are quite right, and the best that can be recommended. Not only may plants that have been grown in pots remain therein, but my limited experience proves that plants which have passed the summer in the open ground are best repotted for the winter. The degree of dryness or dampness to be maintained is a matter of judgment and common sense, either extreme can be avoided. If the potted tubercules get too dry in their outhouse, or on their greenhouse shelf, there are few gardens, public or private, where a little water is not to be had. In the August number of *London Society* I had the pleasure of writing of tuberous Begonias, "Their great recommendation to household horticulturists is, that the varieties which hibernate do so frankly and completely. About November they will flag, and their stems will spontaneously part from the root, as if they were dying; it is no such thing, they are only going to sleep. This is a good time to re-pot them (in light rich soil, half leaf-mould or spent Cucumber-bed and half fresh loam) in larger

pots if required. The plants increase in beauty with age and with the increasing size and strength of the tubercles. You thus get specimen plants with just pretensions to exhibition. The quality and freshness of the soil are mentioned on account of their importance, although in large cities it is often easier to procure new plants than good earth to repot old ones in. If no other source is available, it must be obtained as a favour from some benevolent nurseryman. When repotted, let them take their repose in any snug corner or shelf where it does not freeze. Light or darkness is all one to them then. Keep them dry rather than moist, but not absolutely dry as dust. Too damp they may rot [some varieties rot more readily than others], while excessive dryness will retard their starting in spring. The judicious amateur will hit upon the happy mean, which reminds me of the regretted Van Houtte's recommending for *Genetyllis tulipifera* (a greenhouse shrub with box-like foliage, bearing large cream-coloured foliage striped with red) plenty of air and 'intelligent waterings.' There, indeed, he hit the mark, and gave to the world a golden rule. By 'intelligent' measures great things may be done in the plant way as in other matters." Mr. Smith will see, I hope, that the results of my own small practice scarcely differ from his wide experience. Only I should fear that a cellar would be too damp; but then, again, there are cellars and cellars. Moreover, it is never too late to learn, especially when the teaching is administered with courtesy. Perhaps, therefore, he will confer the additional favour of giving instructions as to the best mode of raising *Begonias* from seed. And I trouble you with these remarks because the beauty and usefulness of tuberous *Begonias* is even yet far from generally known. A recent visit to Bordeaux, Bayonne, and their environs, showed carpet-bedding and vegetable mosaics (favoured by the climate) indulged in to one's heart's content, with plenty of the eternal *Coleus*, *Achyranthes*, and so on (not to be despised in their way), but not even in the well-kept public and botanic garden at Bordeaux were tuberous *Begonias* to be seen. A border of the old *B. discolor* and another of *B. Saundersii*, or something like it, were the only outdoor representatives of the family. Two years ago, in the Amsterdam Zoological Garden, a few Belgian varieties were tried as an experiment. *E. S. D.*

Lapageria alba.—On September 1, 1875, I being then gardener to J. Marshall, Esq., Belmont, Taunton) exhibited a collection of cut blooms, not for competition, at the Bath Horticultural Society's show, and received a First-class Certificate. Among them were two bunches of bloom of *L. alba*, one bunch having thirteen large flowers of great substance, the other eight. The plant from which they were taken was growing in a slate box about 8 feet by 2 feet by 1 foot 6 inches, with a plant of *L. rosea*, and covered the roof of a lean-to house. My experience is, that *L. alba* under good treatment grows much stronger and quite as freely as *L. rosea*, and when grown together as Mr. Westcott states, has a very beautiful effect. Rough peat, charcoal, very little rough loam and leaf-mould, with plenty of water and liquid manure during the growing season, I found suited it admirably. Mr. Marshall's was certainly the best plant I have seen, the foliage being much larger than that of *L. rosea*, much of it being 2 inches to 3 inches across. I moved both plants about four years since from the back wall to the front of the house in which they are growing, after which they made splendid growth, the shift not injuring them in the least, though the roots were disturbed a good deal. *A. Price*.

Is There a Rising Sap?—We tap Maples to rob them of their sap to make sugar. Cut down a Maple while the sap is flowing, and sap continues to run from the trunk. Very little, if any, rises from the freshly-cut stump. Let a frost check the flow, and another thaw will bring very little sap from either stump or trunk. When a Maple is tapped and sap flows at all, the fact is unmistakable that nearly all of it comes from above—little if any from below. The talk of a foreign wisacre has induced the *Rural New-Yorker* to head its editorial leader, "Is there a Descending Sap?" Andrew Murray may "talk like a book," but—

"Why call that poor fellow a saphead?—Does his blood all rise through his toes? What marvel if then it hath hap'ned That sap through his hair overflows!"

I can send you a slip from a plant, if you wish it, that will live for months on the sap which it gathers through its leaves—having neither root nor soil nor water from which to receive it. You can place it in your sanctum, suspended by a thread from a nail or peg, only being careful to keep it from dry winds, sunlight, and excessive cold or heat. Has that plant an ascending sap? Possibly you or Mr. Murray may be able to show another plant which will afford as positive evidence of no descending sap. But if you should, neither your example nor mine would prove that all plants are devoid of circulating sap. *S. Folsom, Alica, N.Y., in American Paper.*

Ampelopsis Veitchii.—It might be worth while to mention that the influence of light has a great deal to do with the bright colouring of the leaves of this plant when on the point of decay. A gardener who visited this place a few days ago was much struck with the bright colour of this plant on a wall, and said it did not colour like that near London, as he had not seen it so fine there. I made mention of the situation (an open east aspect) as having a great deal to do with the colour, taking him to see another plant in a more shady place, which was more like what he had seen; the leaves on that plant are still in a green state, and will, no doubt, fall off without ever assuming the fine red tint. It might also be noted that this plant in its growth upon a wall is greatly influenced in the direction it grows from the light—sometimes growing instead of upwards in the main, as one would suppose, it takes somewhat of a sideways direction. Some of your correspondents may have observed the same thing. Your correspondent, "J. S.," says that, were this an evergreen, it would lose one of its principal charms—the fine autumn colouring. There is no doubt about this; but the fine colouring will in no respect as a decorative subject, I venture to say, compensate for its periods of bareness. In the spring certainly, this *Ampelopsis* is very pretty just when the young buds are showing themselves red all over the bare shoots of the plant. This plant will probably in time be as much or more grown on walls about towns as the ordinary Virginia Creeper is; and for low walls it is much better than it. Your correspondent, "J. S.," says that with him it does not want the slightest attention as regards nailing. Now his experience differs from mine, for although this often clings closely to a piece of the smoothest stone, I have every now and again had to nail shoots that have got from the wall to keep the plants in trim order. I know that some growers, of fancy Ivies for example, cut away every point when it gets away from its moorings, leaving only the shoots that stick firmly of themselves to the wall, thereby doing without nailing. Of course the circumstances of the case should decide whether it is the best plan to cut the points off or nail them in. *R. Mackellar, Abney Hall, Oct. 15.*

Polyanthus Flowers Destroyed by Sparrows. —You have told us lately how to treat Polyanthus plants, but I should be greatly obliged to you or any one for telling me how to remedy the following trouble. I have a garden in Cheshire quite in the country, but near a farmyard. Three or four years ago I began growing Polyanthuses. I bought choice seed and raised a very respectable crop of some thousand plants, which made with other spring flowers a gay display. But unfortunately the sparrows noticed the novelty, and the first year pulled many of the flowers to pieces; the second year they attacked them in bud, and the third year they picked the heart out of the plant directly the buds showed. They even extended their depredations to the common Primroses in the shrubberies, which they had never touched before I grew Polyanthuses. I have tried white cotton all round the plants without effect, then white feathers, which they pull up to line their nests with. I have gibbeted sparrows, which the birds do not mind, and the cats steal. I have even put paraffin and gas-tar on the plants, but the sparrows avoid it, and eat where the plants are clean. I have done all I can by shooting and trapping and taking nests, but the little pests fairly beat me, and I am quite at a loss what to try next, and should be most thankful to any one who would suggest a remedy. *C. W. Dod. [Chain up a cat, giving it a good wire run, near the plants, à la Wilson. EDS.]*

The Potato Crop.—Thanks to the past spell of dry weather we have here succeeded in lifting our crop of many varieties of Potatoes in splendid condition. The two last lots lifted in the week ending on the 13th—Rector of Woodstock and Lapstone, both kinds that usually take the disease severely—are remarkably sound, probably not more than 5 per cent. being diseased. This has been our experience this year with nearly all sorts as grown here in soil of moderate quality and of a light porous nature—in fact, better and cleaner stocks have never been lifted here at any time. On the other hand samples selected with all possible care from the seed stocks, and planted up in rich and retentive soils for the production of fine tubers, resulted in much disease, and in few cases were the samples so good as those produced in the open field. Of kinds that have done remarkably well I may particularise International Kidney, undoubtedly the handsomest and finest white kidney in cultivation; Excelsior Kidney, specially a favourite with the market gardeners for early lifting; Magnum Bonum, a grand late-crop kidney this year, and one that should eventually occupy a high place as a market variety; Schoolmaster, a robust growing white round, of fine quality, and which produced a splendid crop; Blanchard, a very handsome coloured round, and a capital cropper; Rector of Woodstock, the gentle-

man's table Potato *par excellence*; Lapstone, ever a good and useful kind; Early Market, the earliest and best of all white rounds; King of Potatoes, a really fine, useful main-crop Potato; Garibaldi, a heavy cropping and handsome red kidney; Covent Garden Perfection, a much earlier form of the Magnum Bonum. Late American Rose, Scotch Blue, Onwards, and Porter's Excelsior are but a few that have done remarkably well. This is the third year of culture in the same soil, which lies fallow in the winter, and receives but a moderate dressing of manure. The great purpose is to grow clean medium-sized seed samples, and it never fails; but curiously enough, whilst our neighbours' Regents have been heavily hit with disease, we have suffered in but a very minor degree. *A. Dean, Bedford.*

THE ROCK SAMPHIRE.

WE read in Syme's beautifully illustrated *English Botany* that the warm-tasting and aromatic Samphire is frequently used as a pickle. All English persons, a few years in their teens, have heard of it growing on Shakespeare's cliff, for in *King Lear* Edgar says to poor old Gloucester:—

"Come on, sir; here's the place:—stand still. How fearful

And dizzy 'tis to cast one's eyes so low!
The crows and choughs, that wing the midway air,
Show scarce so gross as beetles. Half way down
Hangs one that gathers Samphire,—dreadful trade!
Methinks he seems no bigger than his head:
The fishermen that walk upon the beach
Appear like mice."

The Rock Samphire grows along the south and west coast from Kent to Ayrshire, and on the rocks of more southern shores. It was long since dedicated to the fisherman Saint Peter, and whence its English name by contraction of the Italian *Herba di San Pietro*, to *Sempetra*. The old and more correct spelling was *Sampere*, or *Sampier*, from the French *Saint Pierre*. We beg pardon for all this, which cannot much concern the reader. One of these days there is to be a holocaust of all the stuff hitherto written, except so far as the writings of a few poets and men of science are concerned. We shall then cease to pilfer for awhile and shall have to draw our information as to Samphire direct from the coast. Meanwhile Gerarde says of this plant, which was much used as a condiment in his day, "the leaves kept in pickle and eaten with oil and vinegar is a pleasant sauce for meat, wholesome for the stoppings of the liver, milt, and kidneys;" and Culpepper is of opinion that "ill digestions and obstructions are the cause of most of the diseases which the frail nature of man is subject to," and that they might "be remedied by a more frequent use of this herb." That is what Culpepper says, but whether he copied or wrote from experience we know not. Other writers have recommended the bright green leaves of the Samphire, *Crithrum maritimum*, as a pickle. The plant has been described as "glabrous, green, and very slightly glaucous," its stems are flexuous and fleshy, and the leaves, steeped in boiled vinegar and well spiced, are aromatic and agreeable.

The Samphire has naturally been linked by the circumstances of its growth with stories of shipwreck, for besides fringing the edges of storm-beaten precipices, and growing on the front of cliffs and in the clefts of rock, wherever the dash of the briny spray can reach it, the Samphire is occasionally found on sunken rocks, which at flood tide are almost covered. Its roothold is invariably found near the water, but never in it; it never grows where the submergence is complete. During a violent storm in November, 1821, a vessel passing through the English Channel was driven upon Beachy Head, a rival chalk promontory to Shakespeare's Cliff at Dover. The ship struck and went to pieces, and four only of the crew escaped immediate death by clinging desperately to the partially submerged fragments of the cliff.

During the dark hours of the night the waters boiled round their place of shelter, and the tide appeared to be gaining on them, while the violence of the storm forbade the hope of rescue. For several hours the shipwrecked men listened to the roar of the breakers, awaiting the fate of their companions who had already perished; but the rock they were on produces on its rugged point a few plants of Samphire, and in a moment of terrible suspense one of the poor fellows being on his knees, and grasping the rock to secure himself more firmly, laid hold of the "glabrous,

green, and slightly glaucous" plant, which is so good in pickle, and so intolerant of complete submergence. "Hitherto shalt thou come and no further," was the promise the Samphire offered to those shivering men, and they were not deceived. The tide reached its limit; they heard its hollow sound as the wind fell; light broke, and they saw it retiring; then they saw a boat coming off from the shore; and no doubt the flavour of pickled Samphire recalled to the fancy of these jovial sailors for many a long day the pickle they had themselves been in when soaked with brine on the Sussex coast. *H. Evershed.*

PLANT PORTRAITS.

ALOE TRICOLOR, *Botanical Magazine*, t. 6324.—A dwarf form, with lanceolate white-spotted leaves and panicles of showy red flowers. The flowers are about 1½ inch long, constricted in the middle. Oxford Botanic Garden.

ANEMOPSIS LUDOVICI SALVATORIS, *Gartenflora*, t. 911.—A botanical curiosity, with tufted, stalked, oblong obtuse leaves, pilose on the under surface. The flowers are borne on short spikes provided at the base with a ring of white bracts. Nat. ord., Saururaceæ. Native country, California.

ANTHURIUM TRILOBUM (E. André), *Illustration Horticole*, t. 283.—A tufted stemless species, with long ascending red channelled leaf-stalks thickened at the top, and ovate deeply cordate three-lobed leaves, the central lobe much longer than the lateral one. The plant has not yet flowered, and is supposed to have been introduced from Columbia.

AQUILEGIA CALIFORNICA HYBRIDA, *Floral Magazine*, tab. 278.—One of Mr. Douglas' beautiful crosses between the scarlet *A. californica* and *A. chrysantha*. The flowers are large, with scarlet sepals and yellow petals, terminating in long and slender spreading red spurs. The flowers are very handsome.

ARTHROPODIUM NEO-CALEDONICUM, *Botanical Magazine*, t. 6326.—A Liliaceous plant, with tufted, linear-lance-shaped leaves, barred with black linear markings near the base. The flowers are small, white, and borne on a much-branched, many-flowered panicle. It is a native of New Caledonia, whence it was introduced by Messrs. Veitch.

BEGONIA METALLICA (W. G. Smith), *Gartenflora*, t. 909.—The same species as figured in the *Floral Magazine*, 1876, t. 197. It is a small pink-flowered species, with obliquely cordate, ovate, lanceolate acute pilose leaves. It has been some years in cultivation, but has recently been brought into notice by Mr. B. S. Williams.

BUDDLEIA ASIATICA, *Botanical Magazine*, t. 6323.—A graceful shrub, with lanceolate, finely serrate leaves, and long dense racemes of small white flowers, resembling those of some of the hybrid shrubby Veronicas. It is sweet-scented, and very desirable for stove cultivation. It is a native of India, and was introduced by Messrs. Downie, Laird & Co., of Edinburgh.

FRTLILLARIA DASYPHYLLA and **F. ACMOPETALA**, *Botanical Magazine*, t. 6321.—Two Levantine Fritillarias, already described in our volume for 1875. Interesting to lovers of hardy bulbs.

FUCHSIAS, *Floral Magazine*, t. 277.—The following varieties are figured and described. Mr. Huntley, flowers large, bold, and of the finest form, red tube and sepals, dark violet-purple corolla. Letty Lye, a light variety with delicate flesh-coloured tube and sepals, and deep carmine corolla tinted with purple. Mrs. Huntley has a white tube and flesh-coloured sepals and a large brilliant carmine corolla. Royal Standard has coral-red tube and sepals, and a pale plum-purple corolla. These varieties were raised by Mr. Lye.

GLOIRE DE DIJON, *Journal des Roses*, Oct., 1877.—Were it not for the name on the plate, we should be at loss to know what the Rose intended.

GYMNOGRAMMA HEYDERI (Lauche), *Mauschchrift d. Ver. z. Beford. d. Gartenbaus*, 1877, 421, t. 4.—A new hybrid gold Fern, raised by Herr Lauche, and named in compliment to Herr Heyder, between *G. chrysophylla* and *G. Lauchena*, and remarkable for its broad pinnules and the rich golden colour of the under-surface of its fronds. It is apparently of dwarfish habit, the fronds ovate, with ovate-lanceolate blunt pinnæ, and broad oblong ovate blunt pinnules, the lower of which are pinnatifidly lobate. The colour of the under-surface is a rich golden colour. It comes somewhat near to *G. Lauchena*, but is much

broader in its parts; indeed, except in its dwarfer habit, it exactly corresponds with the *G. Lauchena gigantea* raised in 1869 by M. Stelzner, of Ghent.

INOLIRION PALLASII (Fischer), *Gartenflora*, t. 910.—An Amaryllidaceous plant, with erect stem, some 18 inches high, having linear lanceolate leaves, and producing tufts of stalked pink flowers, each about 2 inches in diameter, composed of six oblong-lanceolate segments. Native of Southern Russia.

LOBELIA LILAC QUEEN, *Floral Magazine*, t. 280.—A seedling of the compacta type, sent out by Mr. B. S. Williams. The habit is very dense and cushion-like, the flowers abundant, and of a bright lilac colour. Presuming the representation to be a faithful one, this plant will be very valuable in the flower garden.

MICROSTYLIS JOSEPHIANA, *Botanical Magazine*, t. 6325.—An Orchid with oblong pseudobulbs, broadly ovate greenish-brown leaves, and terminal racemes of small yellow flowers. It is a native of Sikkim, and is interesting, rather beautiful.

NECTARINE LORD NAPIER, *Florist*, October, 1877.—The popular Nectarine of the day. The fruit is large, roundish oblate, dark red next the sun; flesh pale, highly flavoured; of fine constitution and a good bearer. Under glass it is "the earliest and best Nectarine introduced." It was raised by Mr. Rivers.

ODONTOGLOSSUM TRIUMPHANS and **VAR. LABELLO ALBO**, *Florist*, October, 1877.—*O. triumphans* is well appreciated, and the white-lipped variety only needs to be more known to be equally sought after.

ONCIDIUM EUXANTHINUM, *Botanical Magazine*, t. 6322.—A showy yellow-flowered Oncid, described in our columns in 1869, p. 1158. It was introduced from Brazil by Messrs. Veitch.

PEACH, PRINCESS OF WALES (Rivers), *Revue Horticole*, October 1, 1877.—Fruit globose, of medium or large size, cream-coloured, rose-pink next the sun. Flesh white, vinous, and of pleasant flavour. A freestone. A fine late Peach.

PEAR PASSE CRASSANE, *Bulletin d'Arboriculture*, September, 1877, p. 273.—A fruit of middle-size, rounded-ovoid form, russet-coloured, with yellow spots. Flesh fine, melting, of very good acidulous flavour.

PELARGONIUMS, ZONAL, *Floral Magazine*, t. 279.—The varieties figured are Polyphemus, Tom Bowling, and Leveson Gower—all varieties raised by Mr. Postans, of Brentwood, and distributed by Mr. Burley. Polyphemus is scarlet, with a white eye; Tom Bowling, orange-scarlet; and Leveson Gower, "perhaps the best salmon-coloured zonal yet raised." All three are fine exhibition varieties.

SPHÆROGYNE? IMPERIALIS (Linden), *Illustration Horticole*, t. 284.—Probably a species of *Miconia*, with noble cordate ovate acute leaves, having depressed nerves, prominent on the under surface. The colour is brownish green above, pinkish beneath between the nerves. A very fine stove foliage plant, which has not yet flowered, and whose lineage is, therefore, uncertain. It is clearly Melastomaceous. Introduced by M. Linden.

TACSONIA INSIGNIS, *Revue de l'Horticulture Belge*, p. 217, 1877.—The finest of the Tacsonias, originally published in our columns in 1873. The present figure hardly does justice to the beauty of the plant; the blue colour of the central corona is not sufficiently brought out, or it may be that under some circumstances it is not produced. In any case we are glad to find our verdict confirmed.

NEW ANNUALS.

THERE is no lack of new forms of annuals, though they do not appear to be so numerously produced as they were a few years ago, owing to a declining interest in their culture. No doubt a great deal of rubbish has been put into circulation from time to time, but the chaff has not been unmixd with corn, and some good things have been brought to notice, to the great gratification of lovers of these common flowers. *Leptosiphon rosaceus*, *Godetia Whitneyi*, *Malope grandiflora rosea*, *Godetia Lady Albemarle*, the fine new *Campanula macrostyla*, among others, are cases in point. The season now drawing to a close has brought before the public some things of a highly meritorious character in the way of annuals. Special mention may be made of the glorious *Eschscholtzia Mandarin* and *E. crocea flore-pleno*, obtained by Messrs. James Carter, Dunnett & Beale, and awarded First-class Certificates by the Floral Com-

mittee of the Royal Horticultural Society. Mention has already been made of the fine form of *E. alba flore-pleno*, which is also in the possession of Messrs. Carter & Co., and which will no doubt be seen next summer. Then there are some fine forms of *Dianthus*, of which some four or five varieties were awarded First-class Certificates at Chiswick. It may therefore be said of new annuals, that they have moved on with a prodigious stride during the year of grace 1877.

New annuals in a few cases come to us as foreign introductions; some are raised from seed in this country, but in all probability the greater part are obtained in this country as "selections," Messrs. Carter & Co.'s three fine *Eschscholtzias* are all the results of selections extending over a few years. Great patience and persistency of purpose are required in bringing up these sports to a point when they become fixed types. Sometimes, after three or four years' patient labour, they will flash forth with a brilliancy full of promise for the future, and the next year revert to the original form, and be wholly lost. But many substantial rewards are obtained nevertheless, and labour is sweetened by the valuable results obtained.

Messrs. James Carter, Dunnett & Beale have long made new annuals a speciality, and from their seed farms at Dedham and St. Osyth many new sports among annuals have originated. The men who are constantly at work among the huge masses of annuals are so far observant as to detect any tendency in an annual to sport into a new character. It is immediately marked, the surrounding plants are cleared away, and the attention of the responsible foreman is directed to it. If successive flowers show a continuance of the sport the seed is carefully saved, and the following year it is sown on "stetches," as they are termed, set apart for proving these new forms. Here a further selection is made, and this goes on, it may be, for three or four, six, ten, or twelve years, until the new character is sufficiently fixed to admit of its being distributed.

An inspection of the "new stetches" at the Dedham and St. Osyth farms on two occasions during the past summer afforded opportunities for estimating to some extent the value of some new things growing on them, and for the sake of convenience they are given alphabetically. *Calendula pluvialis sulphurea*, a selection from *C. pluvialis*, is a very pretty type, and in it we have, instead of the dark ring round the eye on a white ground, a golden centre, and the reverse of the petals, instead of being dark, is of a clear sulphur. It is a cheerful and effective annual, and it may be remarked the *Calendulas* are not so much grown as they deserve to be; *Clarkia pulchella*, *Tom Thumb minima*, is a singularly dwarf and compact form, about 4 inches in height, and forming a nice little bush covered with flowers. It is of a pale lilac or fleshy pink colour, and it will make a capital edging to later growing annuals. A counterpart of this in habit, but bearing white flowers, has also been selected. *Clarkia elegans rosea*, double, with rosy salmon flowers of a charming tint, is an improvement in colour on the pretty *Salmon Queen*, and is very fine and effective. *Chrysanthemum bicolor* is one of the pretty annual varieties, white, with a yellow centre and orange ring round the edge; it is very free and striking, and a capital addition to these pretty flowers. *Gilia rosea* is a selection from *G. tricolor*, in which the rose colour takes the place of purple, which gives it a much more effective appearance. Of *Gadetias* several new selections have been made; they are *Godetia Dunnettii Tom Thumb*, which is rather dwarfer than the parent from which it is selected, and the flowers are of a deeper and more pleasing shade of colour; the habit of the plant is also much improved, and instead of blooming in irregular spikes of varying heights it is of a compact nosegay form, displaying its flowers much better. Then of *G. reptans*, a somewhat prostrate-growing form obtained from Texas, the following new selections have been obtained, viz.:

—*alba grandiflora*, pure white, flowers double the ordinary size; delicate rose or pink stamens; *insignis*, large white flowers, with a brilliant carmine spot on each petal, a good successional bloomer, commencing at the base of the plant and gradually spreading over it; *insignis Tom Thumb*, a dwarf form of *insignis*, of a flat growth and of a compact habit; and *Lindleyana*, having self violet or rosy purple flowers destitute of any spot, growing from 12 to 15 inches in height, very free and effective in appearance. *Leptosiphon*

androsaceus ruber is a selection from *L. androsaceus*, with pretty reddish purple flowers of a bright and effective hue of colour. *Nemophila maculata marginata* is a large form of *N. maculata*, but with the purple spot broadened out into a distinct broad margin of this colour. This is very attractive when true to the new character, and if it can be fixed will be a valuable acquisition. *N. discoidalis rosea* has the dark ground changed to bright rose, and being of a compact growth and free blooming it is very attractive. *N. discoidalis fol. variegata* has a silvery variegation in the foliage, in which respect it is a very good companion to the golden variegated *N. maculata*, and both are very pretty in early spring, when the variegation is seen to the best advantage.

The foregoing list does not include all the selections being made, because many sports have only put in appearance here during the past year or two, but they include those that have approached to something like fixity of character, and in all probability will be grown when distributed. *R. D.*

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, OCT. 17, 1877.

Oct. 11.—A very fine day. Cold and windy. Heavy showers of rain in early morning.
 12.—A fine day. Cloudy at times. Little rain fell at night.
 13.—A dull cloudy day. Strong wind. Fine and clear at night. Rain fell in morning.
 14.—A very fine summer-like day. Warm. Gale at night.
 15.—A fine bright day. Little rain fell in morning. Violent gale in early morning.
 16.—Fine and cloudless till 10 A.M., then overcast till 6 P.M. Cloudless at night. Rain fell between 11 A.M. and 1 P.M. Cold.
 17.—A fine bright day, partially cloudy. Very cold.

^a The barometer reading at 3 P.M. was 29.59 inches. At midnight it was 29.33 inches; and at 9 A.M. on the morning of the 15th was 29.53 inches.

LONDON: *Barometer*.—During the week ending Saturday, October 13, in the vicinity of London the reading of the barometer at the level of the sea decreased from 30.63 inches at the beginning of the week to 30.17 inches by the morning of the 8th, increased to 30.33 inches by noon on the 9th, decreased to 29.93 inches by the morning of the 11th, increased to 30.04 inches by the morning of the 12th, decreased to 29.87 inches by the morning of the 13th, and was 29.88 inches at the end of the week. The mean reading for the week at sea level was 30.12 inches, being 0.14 inch below that of the preceding week, and 0.23 inch above the average.

Temperature.—The highest temperatures of the air observed by day varied from 61½° on the 13th to 53½° on the 7th; the mean value for the week was 50½°. The lowest temperatures of the air observed by night ranged from 36½° on the 7th to 46° on the 13th; the mean for the week was 42°. The mean daily range of temperature in the week was 14½°, the greatest range in the day being 17½° both on the 7th and 10th, and the least 11½° on the 8th.

The mean daily temperatures of the air and the departures from their respective averages were as follows:—7th, 44°, —8° 6; 8th, 49° 5, —2° 7; 9th, 46° 9, —5° 10th, 45° 2, —6° 4; 11th, 49° 6, —1° 7; 12th, 50°, —1°; 13th, 54° 1, +3° 4. The mean temperature of the air for the week was 48° 5, being 3° 1 below the average of observations extending over a period of sixty years.

The highest readings of a thermometer with black-

ened bulb in vacuo, placed in sun's rays, were 108° on the 11th, 103½° on the 9th, and 104½° on the 13th; on the 7th the reading did not rise above 71°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 28° on the 7th and 29½° on the 10th. The mean of the seven low readings was 35½°.

Wind.—The direction of the wind was N., W., and S.W., and its strength brisk. The weather during the week was fine and cold, but generally cloudy. Fog prevailed on the 7th, and a solar halo was seen on the 12th.

Rain fell on three days during the week, the amount collected was 0.35 inch.

ENGLAND: *Temperature*.—The highest temperatures of the air observed by day were 65° at Sheffield, 64½° at Eccles, and 63½° at Cambridge; the highest temperature of the air at Wolverhampton was 56½°, and at Bradford 58½; the mean value from all stations was 61°. The lowest temperatures of the air observed by night were 31½° at Wolverhampton, 32° at Nottingham, and 33° at both Bristol and Eccles; the lowest temperature of the air at Bradford was 41½°, and at Leeds, 41°; the general mean from all stations was 36½°. The range of temperature was the greatest at Eccles, 31½°, and the least at Bradford, 17½°; the mean range from all stations was 24½°.

The mean of the seven high day temperatures was the highest at Truro, 60°, and Portsmouth, 58½°, and the lowest at Wolverhampton and Nottingham, both 53½°; the mean value from all stations was 56½°. The mean of the seven low night temperatures was the lowest at Wolverhampton, 37½°, and Bristol and Eccles, both 39°; and the highest at Portsmouth and Sunderland, both 44½°; the general mean from all stations was 42½°. The mean daily range of temperature in the week was the least at Norwich and Bradford, both 10½°, and the greatest at Eccles, 18½°; the mean daily range from all stations was 14½°.

The mean temperature of the air for the week from all stations was 48½°, being 7½° lower than the value for the corresponding week in 1876. The highest was 51° at Truro, and 50½° at Portsmouth, and the lowest 44½° at Wolverhampton.

The amounts of rain measured during the week at the several stations varied from one inch nearly at Eccles, and three-quarters of an inch at Sheffield, to one-tenth of an inch at Brighton, Plymouth, and Bristol; the average fall over the country was four-tenths of an inch.

The weather during the week was fine, although dull and gloomy at times. Lightning was seen at Cambridge on the 10th.

SCOTLAND: *Temperature*.—The highest temperatures of the air observed by day varied from 67° at Greenock to 58½° at Aberdeen; the mean value from all stations was 60½°. The lowest temperatures of the air observed by night ranged from 33° at Perth to 36° at both Glasgow and Greenock; the mean value from all stations was 35°. The mean range of temperature in the week from all stations was 25½°.

The mean temperature of the air for the week from all stations was 48°, being 4½° lower than the value for the corresponding week in 1876. The highest was 49½° at Greenock, and the lowest 47° at Edinburgh.

Rain.—The amounts of rain measured during the week varied from 3 inches at Greenock to six-tenths of an inch at Edinburgh, Dundee, Aberdeen, Leith, and Perth; the average fall over the country was 1 inch.

DUBLIN.—The highest temperature of the air was 66½°, the lowest 37°, the range 29½°, the mean 51½°, and the fall of rain ¼ inch

JAMES GLAISHER.

Law Notes.

LIABILITY OF SHIPOWNERS.—At the City of London Court a few days since the case of *Suter v. Walkins* was heard, in which the plaintiff, an importer of Potatoes in the City, sued the defendant, the owner of the ship *Lightning*, to recover the sum of £10 13s. 1d. for the non-delivery of thirty-eight sacks of Potatoes from the defendant's ship in the London Docks. From the plaintiff's statement it appeared that he had consigned to him from abroad 3860 bags of Potatoes, and that when they were tallied thirty-eight bags were found wanting, for the value of which the present action was brought.—George Wynn, a lighter-man, said he found thirty-eight bags short, and complained both to the mate of the ship, as well as to the stevedore, of the deficiency, and refused to sign for the full delivery of the sacks. The plaintiff's foreman said he checked the sacks on their delivery at his wharf, and found the number sued for deficient.

At this stage of the case the defendant's solicitor

urged that his client's contract was completed as soon as the sacks were delivered into the barge alongside.

The learned Judge said he did not think so. They might have been stolen in the river. In the days of "good Queen Bess" river robberies were punishable by death; he was glad it was not the case now.

This being the plaintiff's case, John Cogne, the defendant's stevedore, said he knew the mark of the Potatoes, and they tallied with the ship's manifest.

The Judge recalled the first witness, who said he only tallied 1300 sacks, but the plaintiff's foreman checked the rest.

The learned Judge said that as the mate of a ship and the ship's stevedore were the *bond fide* agents, with the captain, of the owner of the ship, the owner is responsible for their actions. In the present action he considered that the plaintiff had proved his case, and therefore judgment would be in his favour.

The owner of the ship was about to address the Court, when Mr. Commissioner Kerr told him to stand down, as judgment had been given against him. Judgment was accordingly entered for the plaintiff, with the costs of solicitor and two witnesses.

Variorum.

FIR TREES IN BRAEMAR.—In the beginning of this century Dr. Skene Keith tells us there were thousands of Fir trees in Braemar, some of which were nearly 6 feet in diameter, "superior in point of quality to any wood of that denomination that was ever imported into any place in Great Britain." Dr. Macgillivray in his *Natural History of Braemar*, throws doubt on this statement, but Dr. Lankester points out that between 1811 and 1850 the finest part of the Braemar Pines were sold and cut down. Mr. J. B. Webster states that on Locknagar he found the remains of old Fir trees at an elevation of 2500 feet above the sea level. From the appearance of the roots and trunks he supposed them to have averaged from 6 to 12 inches in diameter above the surface of the ground. He also found the remains of an Oak tree at an elevation of 1000 feet above the sea level. The average diameter of the trunk was 24 inches (*Transactions of the Highland and Agricultural Society*, 1859-61, p. 285). The lower division of Mar, between the Dee and Don, from the coast about 15 miles backward, was, according to Dr. Skene Keith, almost a continued forest, distinguished by the names of the Forest of Drum, the Forest of Kintore, and the Forest of Stocket. Mr. Cosmo Innes, while doubting whether in old historical Scotland—Scotland of the fourteenth to the beginning of the eighteenth century—there was more wood than at present, states that we have now, as we have always had, in the glens of Mar and elsewhere, a very interesting, and, as he believes, aboriginal Pine forest of *Pinus sylvestris* (Scotch Fir), no matter whether living to its natural term or meeting with a violent death, still reproducing itself if not impeded, and indeed surmounting many impediments, and stretching up, not, as vainly imagined, to the tops of the mountains, but as high up the glen as wood can ever have grown—as high as soil and climate will allow. *Aberdeen Paper*.

THE BEST CROPPING HARDY FRUIT TREES.—The general failure of the fruit crops this year will doubtless make all those who intend to plant young trees try to find out the varieties that have borne the best crops in their different localities. To begin with Apples, the best-bearing varieties here have been, amongst the early ripening, the Irish Peach, Early Harvest, and Early Strawberry; of the mid-season sorts, Lord Suffield, Duchess of Oldenburg, Cox's Pomona, Small's Admirable, King of the Pippins, and Cox's Orange Pippin; and of the late or winter-keeping sorts, New Hawthornden, Tower of Glammis, Blenheim Pippin, Lord Burghley, Dumelow's Seedling, and Sturmer Pippin have cropped the best. The early varieties of Pears that have had half a crop on them have been Beurré Giffard, Clapp's Favourite (an American Pear of good flavour), Beurré d'Amanlis, and Williams' Bon Crétien; of the mid-season Pears, Louise Bonne of Jersey, Foudante d'Antonne, Doyenné du Comice, Thompson's and Comte de Lamy; and of the latest Knight's Monarch, Ne Plus Meuris, Beurré Easter, and Hacon's Incomparable. All kinds of Plums have been a complete failure, that great bearer in most years, the Victoria, having only very thin crops even in the most sheltered situations. Of Cherries, although I never saw the bloom more abundant, only the May Duke and Morellos on the walls produced crops. There is not the least doubt but that by the selection of free-bearing hardy fruit-trees in planting new orchards and waste grounds, the production of fruit in this country might be doubled, and a check put to the importation of so much hardy fruit from abroad to our markets. Of course, in unfavourable seasons like the present the foreigners,

from their better climate, would always have the advantage of our growers, and the higher prices given them for fruit would compensate them for the carriage; but in plentiful fruit years here this will not be the case. If new orchards planted with the free-bearing sorts of Apples, Pears, and Plums were attached to farms that had only old, unproductive ones, and all waste grounds and even hedge-rows were planted in places out of the reach of the million what quantities of fruit might be grown, and then the markets might be supplied at a cheap rate. The best-cropped small orchard I have seen this year was where there had been a quarry, and the debris of the magnesian limestone surface had been placed in it to fill it up. The tenant, an industrious man, had barrowed and carted all the road-scrapsings within his reach to plant the trees in, and they had seldom missed bearing fine fruit. Of small hardy bush-fruit, such as Gooseberries, Currants, and Raspberries, there might be greater quantities grown in odd corners, in gardens and orchards, and in waste places. That delicious and wholesome fruit, the Strawberry, seems to be increasing in its more extended cultivation, and every large town and city will yet come to have its strawberry farms or gardens. *William Tillery, Welbeck, in "Florist and Pomologist."*

A VENERABLE WILD CHERRY TREE.—The *Irish Farmers' Gazette* remarks in its last issue that visitors to Old Conna Hill, the charmingly situated residence of Phineas Riall, Esq., D.L., could not fail to be impressed with the huge size and proportions of a venerable wild Cherry Tree which stands in isolated grandeur on an elevated plateau of greensward immediately in front of the house. It would be hazardous to guess even as to the age of this grand, old ancestral tree; but, at all events, a long page has been furnished for the world's history since the sapling Cherry first raised its head sufficiently to look down on its beautiful surroundings. Full of foliage and, apparently, of vigour, it looked in the early part of the season—when calling at Old Conna—as if it would continue, for long years to come, to be an object of interest. It was with regret, therefore, that we found on occasion of a recent visit to Old Conna that one of the huge limbs had suddenly given way, owing to decay at the centre, where the water found a lodgment and a way in. The loss of this great arm has taken considerably from the size and spread of the tree, as well as marred its symmetry. Nevertheless, we hope it will long remain as one of the most prominent of the many objects of interest to the arboriculturist to be found at Old Conna, and the most remarkable example we know of the size to which the Cherry will grow to. Fearing, however, that the venerable patriarch may succumb, or his removal be necessitated, through fear of accident from the sudden crash of another great limb, we have thought it well to put upon record the dimensions of the trunk—the height at top and spread of branches we cannot state exactly. At 1 foot from the ground the circumference of the trunk is 16 feet 8 inches; at the ground surface considerably more, owing to large irregular expansions and excrescences. At 5 feet from the ground it branches out, and here the girth is 19 feet! Will any of our readers kindly say if they know of any other tree of its kind that exceeds these measurements? Dr. MOORE—who has often admired its huge proportions and picturesque form, and who, with the writer, lamented over the loss of limb and the insidious symptoms of decay—stated that in all his wanderings in these and other lands he never met any of its kind at all coming up to the proportions of Mr. Riall's picturesque and patriarchal Cherry tree.

HUMEA ELEGANS.—A most graceful and elegant biennial is the *Humea elegans*, not so much grown as it deserves to be. It is, moreover, of very easy culture. The seed should be sown in May, and put into a gentle hotbed. The seed should be very lightly covered, and if a piece of glass be put over the pot, it will keep the soil moist, without too much watering, until the seeds germinate. As soon as the plants are sufficiently large to handle, they should be potted off into small pots, and put back into a gentle heat. When the plants begin to fill the pots with roots, they should be shifted into 48-sized pots, using a compost of loam, peat, and sand. The plants when potted should again be put back into a gentle heat. With attention they will now begin to grow rapidly, and will soon require another shift, when a little rotten dung should be mixed with the compost, and less peat used. The plants, when shifted, may now be placed in a light, airy part of the greenhouse, near the glass, and should be well attended to in regard to watering, being also occasionally syringed in the afternoon. About the first or second week in August the plants should have their final shift for the season. If they have done well, they should now have 8-inch pots, and more rotten dung and less peat should be mixed with the compost. Towards the middle of October the plants should (if properly handled) be from 18 inches to 24 inches high, and every leaf should be perfect. During the autumn and winter

months they should occupy a warm and light part of the greenhouse. They may, of course, be wintered anywhere, if frost be kept out, but they will do best in a light and warm part of the greenhouse, as recommended above. During the autumn and winter months no more water should be given than is absolutely necessary to keep them from suffering for want of it. Towards the end of February they should be put into 10-inch or 12-inch pots, using a compost of half loam and half dung, with a little sand. As the days lengthen, and heat increases, the plants will begin to grow freely. When first shifted they will not require much water until they begin to fill the pots with fresh roots, when water should be liberally supplied to them. Towards the end of May they will be beautiful objects, and may be plunged in the most suitable places in the flower garden. They should not be planted in very exposed places, though they will stand a fair share of wind, and, being securely tied to neat stakes, they will be very ornamental till the end of the summer season. *M. Saul, Stourton, in "Florist and Pomologist."*

Enquiries.

He that questioneth much shall learn much.—BACON.

211. GALVANISED IRON WIRE.—Has galvanised iron wire an injurious effect on vegetation? I have some Roses and some Raspberries trained to galvanised wire: in both cases the shoots appear to me to suffer when tied to it. *N. E. L. L.* [We have not observed the injurious effect complained of. What do our correspondents say? Eds.]

212. GALVANISED CORRUGATED IRON.—Can any of your readers give me any practical information as to the utility and cheapness of galvanised corrugated iron for the roofing of cottages? What I want to know is whether it will compare favourably with slates. The former, of course, will take much less material for rafters, &c. *H. Maxwell, Selborne.*

Answers to Correspondents.

ADDRESS WANTED. Can any one give us the present address of the manufacturers of Brooks' Liquid Carbolic Soap—the Clydesdale Co., formerly of the Imperial Works, Three Mills Lane, Bromley-by-Bow, E.

BURNING CLAY. A correspondent lately asked a question as to the cost of burning clay, and we may state as a result of our inquiries that in the neighbourhood of London the cost is 3s. a yard.

EXCRESCENCE ON BEECH LEAVES. *H. M.* The excrescence is produced by *Cecidomyia piligera*. *A. M.* FUNGUS: *F. Kidd.* Fungus of any kind is generally regarded with suspicion when it gets near the roots of anything. You had better put your Vine roots on the safe side by removing the whole, or as much as possible of it, before it spreads to any great extent.

GYMNOGRAMMA: *J. Hudson.* It is probably a symmetrical sport from *G. pulchella*; and the tasselled apices of the frond and of the pinna are very ornamental. It may be called *G. pulchella cristata*, and is well worth perpetuating if it will keep constant, as it probably will do.

INSECTS: *E. H.* *Steropus madidus*, a carnivorous hunting beetle, consequently more a friend than a foe to the gardener. *A. M.*—*Campse*. The moths from your cellar are not clothes moths, which are considerably smaller; but your insects are too much rubbed to be determined. *J. O. W.*—*R. F.* The lice from the old wood of Willows (which do not touch the young shoots or leaves) are a large species of aphides (*A. salicis*). They are not at all common. *J. O. W.*

LILY OF THE VALLEY: *T. E.* In forcing Lily of the Valley successfully the first essential is to procure strong roots that have the flower-buds fully developed, such as are now imported from Holland and Germany. This plant, as too often grown in England in out-of-the-way corners, shaded by the branches of trees, and the soil exhausted by their roots, is not in a condition to force well; not but that roots for forcing can be well cultivated in this country if proper attention is paid to them. If required early, say in January, the roots should be potted from a dozen to a score together in 6-inch pots, sufficiently drained, in ordinary soil. This may be done next month, and the pots plunged in ashes and covered overhead with the same material, as usually practised with Hyacinths and other bulbs. Three weeks or a month before they are wanted they ought to be plunged in a bottom-heat of 75° or 80°, and the light kept from them for a fortnight, until they have pushed up an inch or two, after which they should be moved to a house near the glass, gradually, not all at once, subjecting them to the light, with a temperature of 65° in the night and proportionately higher by day. If there is not convenience for submitting them to the above temperature they will do equally as well cooler, of course requiring more time.

NAMES OF FRUITS: *G. W.* Pear: *Beurré Rance*. Apples: 1, *Mishull Crab*; 3, *Nonsuch*; 4, *Cellini*; 5, *Mère de Ménage*; 6, *Court of Wick*; 9, *Royal Russett*; 10, *Royal Pearmain*; 11, 17, *Dumelow's Seedling*; 13, *Hollandbury*; 16, *Fearn's Pippin*; 18, *Cox's Orange Pippin*; the others not recognised.—*E. B. C.* 1, *Margil*? 2, *Court of Wick*; 4, *Shepherd's Newtoning*; 5, *Dutch Codlin*; 7, *Hawthornden*; 8, *Downton Pippin*; 9, *Royal Russett*; 10, *King*

of the Pippins; 11, not recognised, but not Norfolk Beaufin; the others not known.—*T. N. K.* 1, *Northen Greeting*; 2, *Rymer*; 3, *Braddick's Nonpareil*; 4, not known; 5, *New Hawthornden*? 6, *Hollandbury*.—*John Charlton.* Your Apple is not known.

NAMES OF PLANTS: *W. C.* We cannot spare time to hunt up the names of plants of which solitary leaves only are sent to us.—*B. B.*, *Queenstown*. 1 and 2 seem to belong to *Araliaceae*, but they are not determinable from leaves only; 3, *Spiraea callosa*.—*J. M. W.* *Aralia spinosa*, a hardy deciduous plant from Virginia.—*A. W.* The plant received from the Sandwich Islands is *Asclepias curassavica*.—*A. T.* *Melilotus alba*.—*R. D.* *Euonymus latifolius*.—*P. M.*, *St. Leonards*. *Salix caprea*.—*P. T. N.* *Abelia serrata*.—*E. B. C.* 1 and 2, *Anthuriums*, not determinable; 3, a species of *Higginsia*; 4, *Tetramena mexicanum*; 5, *Lamprocarum fulgens*; 6, *Gesnera* or *Episcia*, we cannot say which without flowers; 7, *Beloperone oblongata*? Could you oblige us with a good specimen of the latter for the herbarium?—*W. B.* 1, perhaps an *Echeveria*, but not determinable without flowers; 2, *Selaginella Martensii*; 3, *Peperomia arifolia*; 4, may possibly be a *Boussingaultia*, but indeterminate in the absence of flowers; 5, *Linaria spurea*.—*H. M. K.* *Odontoglossum Rossii*.—*T. B. W.* 1, *Aeschynanthus grandiflorus*; 2, *Diplacus (Mimulus) glutinosus*; 3, *Lycycteria formosa*.

PEAR LEAVES: *H. Barnard.* It is the well known fungus, *Rostelia cancellata*. You must burn the leaves, but we fear it is too late this year, as the spores have probably fallen to the ground. *M. J. B.*

SCABBY POTATOS: *Inquirer.* The scab on the Potato is only skin-deep, and is now generally ascribed to the action of the earthworms, which in dry weather excoriate the skins of the tubers to obtain moisture. Your best remedy would probably be found in the application to your Potatos, and early in the spring, of a dressing of agricultural salt sown broadcast over the surface and dug in. Also use when planting the sets a light dressing of soot. Both of these ingredients are excellent fertilisers, yet obnoxious to the worms.

VARIOUS: *Piccicola.* The name of the creeper is *Ampelopsis tricuspidata*, generally called in gardens *A. Veitchii*. We do not know which species of *Aloe* you allude to, but as a rule none of them flower every year under cultivation. The *Pampas*-grass should not be cut down level with the ground when the bloom is over, nor should it be cut at any time, except, it may be, occasionally to remove the dead leaves from the bottom.

WORCESTER PEARMAIN APPLE: *J. Scott.* We find, on inquiry, that this Apple is not the same as the old Scarlet Pearmain. The Worcester Pearmain is ripe in August, two or three months before the Scarlet Pearmain, and the eye is also different, being small, with short closed segments set in a shallow and uneven basin, whereas in the Scarlet Pearmain it is open, with long reflexed segments.—*E.*

Markets.

COVENT GARDEN, October 18.

Our market is completely overdone with Apples just now, large quantities remaining on hand, prices for common sorts being exceptionally low. Grapes are heavy, but Pines meet with a ready sale. Kent Cobs are easily cleared at firmer rates. *James Webber, Wholesale Apple Market.*

SEEDS.

LONDON: October 17.—The seed market has this week been rather thinly attended, and the business doing has been limited in extent. The article now most in request is Trefoil, for which there is a good speculative inquiry at an advance of 1s. to 2s. per cwt. In Red Clover there is no movement at present, either up or down; in despair of obtaining orders, the French, and especially the Americans, have during the last few days offered less freely to this country. On account of its cheapness, foreign Italian meets with rather more attention. Rape seed is fairly steady at the recent fall, but in white Mustard the downward tendency still continues. New brown Mustard has now begun to offer in quantity. Feeding Linseed is firmer. For white Millet, which is now largely used as a substitute for Canary seed, there is a good sale at the moderate values now current. Blue Peas and Haricot Beans are in good request at last Monday's rates. For winter Vetches the trade keeps very slow, and quotations are again lower; in fact, good samples are now obtainable on Mark Lane at unusually low prices. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.*

CORN.

At Mark Lane on Monday English Wheat was held for better prices at the opening, but as the day advanced it was found advisable to submit to the level of the previous Monday's quotations. Foreign Wheat was steady, without much demand. Barley was in limited request, and for grinding parcels prices were hardly as good. Malting Barley remained firm. Malt was quiet, and as regards the new produce, of which there was a fair supply, prices were somewhat unsettled; 70s. per quarter was about the top quotation. Oats were a little cheaper, while in the value of Maize there was no particular alteration. Beans and Peas were taken off at firmer prices. Flour was scarcely so firm.—Trade on Wednesday revealed no particular feature. Holders mostly continued firm, but buyers appeared few and far between, and the result was that, in the majority of sales effected, any difference in prices as compared with the rates of Monday was disadvantageous to the factor.—Average prices of corn for the week ending October 13:—Wheat, 52s. 2d.; Barley, 43s. 6d.; Oats, 23s. 9d. For the corresponding period last year:—Wheat, 46s. 2d.; Barley, 39s. 5d.; Oats, 25s. 10d.

CATTLE.

At the Metropolitan Market on Monday the demand for beasts was fair, and prices recovered from last Thursday's depression. The supply of sheep was small, yet enough for the demand—trade being exceedingly dull for any but choicest descriptions. Some choice sizeable qualities reached 7s., but our quotations more truly represent the average. There were very few calves on offer, and choice ones were in demand. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 6d. to 6s.; calves, 4s. 8d. to 6s.; sheep, 5s. 4d. to 5s. 8d., and 6s. 4d. to 6s. 10d.; pigs, 4s. to 5s.—On Thursday trade, though very quiet, was tolerably steady, owing to the cold weather. The supplies, both of beasts and sheep, were about the average for a Thursday. Fine breeds were firm, with a moderate demand, but other kinds sold slowly. Calves were quiet but steady.

HAY.

The quotations from the Cumberland Market are as follows:—Superfine meadow hay, 105s. to 115s.; inferior, 84s. to 95s.; superior clover, 130s. to 140s.; inferior, 90s. to 112s.; and straw, 54s. to 60s. per load.—At Whitechapel, on Thursday, a moderate supply of hay and straw was on sale. There was a good trade, and prices were well supported. Prime old Clover, 100s. to 142s.; inferior, 85s. to 95s.; good new, 100s. to 135s.; prime meadow hay, 90s. to 113s.; inferior, 70s. to 85s.; and straw, 44s. to 55s. per load.

POTATOS.

We learn from the Borough and Spitalfields markets' reports that good Potatoes, of which there are only moderate supplies, continue in request at full prices. Inferior Potatoes are a heavy sale. Kent Regents, 120s. to 140s. per ton; Essex ditto, 100s. to 130s.; rocks, 90s. to 100s.; kidneys, 110s. to 130s.; Victorias, 120s. to 140s.; American Rose 100s. to 120s.—The imports into London continue to increase in bulk. Last week 45,134 bags were received from Hamburg, 8171 Antwerp, 7622 Bremen, 2450 bags 281 sacks Boulogne, 3862 bags Ghent, 2087 Dunkirk, 2516 Harlingen, 712 Stettin, 660 Rotterdam, and 140 Brussels.

B G L OILCAKE.

ARREST YOUR PURCHASES
of all other Cake until you have read the "Book of Testimonials" from users of this cake. Sent post-free by the Agent for the County, or by the Makers.
Mills, Shad Thames, London, S.E.

GISHURST COMPOUND.
Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight, in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s., 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited).

RUSSIA MATS, for Covering Garden Frames.—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post-free on application.
JAS. T. ANDERSON, 149, Commercial Street, Shoreditch, London, E.C.

RUSSIA MATS.—A large stock of Archangel and Petersburg, for Covering and Packing (price on application for Archangel)—Petersburg, 60s. to 100s. per 100; superior close-wove, 40s., 50s. and 55s. per 100; Packing Mats at 20s., 30s., and 35s. per 100; and all other descriptions of Mats at equally low rates, at
J. BLACKBURN AND SONS, 4 and 5, Wormwood Street, London, E.C.

PRELIMINARY ANNOUNCEMENT. IMPORTANT AUCTION SALE.

PATENT PAXTON INDEPENDENT BOILER.
"TUBULAR" and EVERY OTHER BOILER of known Merit of Excellence.

RUSSIA MATS for Covering from Frost, from 30s. to 70s. per 100: good for packing from 20s. GUNNY BAGS, from 3 1/4 each. Delivered free to any station in London.

SUTHERLAND, SON AND CO., 21, Fenchurch Buildings, Fechurch Street, London, E.C.

Wholesale Russia Mat Merchants. NEW ARCHANGEL MATS, ST. PETERSBURG MATS, of all qualities and sizes. RAFFIA FIBRE, &c. Firms are requested to send cash or reference in first transactions.

ROLL TOBACCO PAPER and CLOTH, genuine, in 2lb. and 4lb. packets, best quality only. Trade cash price very low, and sample sent on application. J. GEORGE, Putney Heath, London, S.W.

RUTLEY AND SILVERLOCK, 412, Strand, W.C., beg to intimate, in reply to numerous enquiries, that they expect a consignment of the above article, which was favourably noticed in the Gardeners' Chronicle of September 22, in APRIL or MAY NEXT. Price 21s. per cwt, in original packages of about 1/2 and 1 cwt. Earliest orders will be supplied from first arrival.

HORTICULTURAL WINDOW GLASS. A large variety of sizes, 15-oz., 12s. 6d.; 21-oz., 16s. 6d. per 100 feet. Large sizes, in Cases, for Cutting up—15-oz. 4ths, 36s.; 3ds, 46s. per 300 feet—21-oz. 4ths, 36s.; 3ds., 46s. per 200 feet.—ALFRED SYER, Glass, Lead, Zinc, Oil, and Colour Merchant, 8, Pentonville Road, London, N.

Rosher's Garden Edging Tiles. THE ABOVE and many other PATTERNS are made in materials of great durability. The plainest sorts are specially suited for KITCHEN GARDENS, as they harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do "grown" Edgings, consequently being much cheaper.

GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design. F. ROSHER AND CO., Manufacturers, Upper Ground Street, Blackfriars, S.E.; King's Road, Chelsea, S.W.; Kingsland Road, E. Agents for LOOKER'S PATENT "ACME FRAMES," PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT BEADED GARDEN WALL BRICKS.

ORNAMENTAL PAVING TILES, for Conservatories, Halls, Corridors, Balconies, &c., from 3d. per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection.

WHITE GLAZED TILES, for Lining Walls of Dairies, Kitchens, Kitchen Ranges, Baths, &c. Grooved and other Stable Pavings of great durability, Wall Copings, Drain Pipes and Tiles of all kinds. Roofing Tiles in great variety. Slates, Cement, &c. F. ROSHER AND CO., Brick and Tile Merchants. See addresses above.

SILVER SAND, fine or coarse grain as desired. Prices by Post per Ton or Truck-load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post. FLINTS and BRICK BURS for Rockeries or Ferneries. KENT PEATS or LOAM supplied at lowest rates in any quantities. F. ROSHER AND CO.—Addresses see above. N.B.—Orders promptly executed by Rail or to Wharves. A liberal Discount to the Trade.

Indestructible Terra-Ootta Plant Markers. MAW AND CO.'S PATENT.—Prices, Printed Patterns, and Specimens sent post-free on application; also Patterns of Ornamental Tile Pavements for Conservatories, Entrance Halls, &c. MAW AND CO., Benthall Works, Broseley.

WOOD TRAINING STICKS and TALLIES, commended by Royal Horticultural Society. BAMBOO CANES, RAFFIA for tying, VIRGIN CORK, ARCHANGEL and other MATS, PACKING MATS, &c. Wholesale prices on application to C. J. BLACKITH AND CO., Cox's Quay, Lower Thames Street, London, E.C.

LABELS. Secure Tree and Plant Labels. PARCHMENT or CLOTH LABELS, TREE or PLANT LABELS, punched parchment, 4 inches long, 3s. 6d. per 1000, or 30s. per 10,000; if eyeleted, 4s. per 1000. Vellum cartridge, 4 inches long, 3s. per 1000 for 10,000. Sample Labels sent on receipt of postage stamp. Orders delivered free in London. FISHER, CLARK AND CO., Label Works, Boston.

Under the Patronage of the Queen. J. SMITH'S IMPERISHABLE STRATFORD LABELS.

The above Labels are made of a White Metal, with RAISED BLACK-FACED LETTERS. The Gardeners' Magazine says:—"We must give these the palm before all other plant labels, as the very first in merit." Samples and Price Lists free.

J. SMITH, The Royal Label Factory, Stratford-on-Avon.

Metallic Hothouse Builder to Her Majesty. HENRY HOPE (late Clark & Hope, formerly Clark), HOTHOUSE BUILDER and HOT-WATER APPARATUS ENGINEER, 55, Lionel Street, Birmingham. Established A.D. 1818.

Advertisement for T.H.P. & Co. Dennis, Anchor Iron Works, Chelmsford. Features a large illustration of a conservatory and text: 'THE HUNDRED GUINEA CONSERVATORY', 'OFFICES MANSION HOUSE BUILDINGS & C.', 'ART-WITH-ECONOMY-APPLIED-TO-CONSERVATORIES'.

In consequence of the increasing demand for Conservatories, in which pure art is combined with moderate cost, T. H. P. DENNIS & Co. have been led to introduce designs of a character hitherto unknown. One of these designs, showing a house 22 feet 6 inches X 13 feet 6 inches, is annexed, and the result, as regards the extremely low price (which includes fixing, glazing, painting, carriage, &c.), has been attained only by special machinery and a system of interchangeable parts. T. H. P. DENNIS & Co. are also prepared to provide and fix Hot-water Heating Apparatus and Horticultural Buildings of any dimension or description. Full-sized specimens of Greenhouses, &c., and Hot-water Apparatus in work, can be inspected at Mansion House Buildings, London, E.C. Gentlemen waited upon at their residences by experienced designers. Estimates and Plans free.

BELGIAN GLASS for GREENHOUSES, &c.,

Can be obtained in all sizes and qualities, of
BETHAM & SON,
 9, LOWER THAMES STREET, LONDON, E.C.
 B. & Son have always a large Stock in London of 20-in. by
 12-in., 20-in. by 14-in., 20-in. by 16-in., in 16-oz. and 21-oz.

AVELING & PORTER'S ENGINES have gained the highest
 Prizes at every important International Exhibition. The two
 Medals for Progress and Merit were awarded them at Vienna
 for their STEAM ROLLERS and ROAD LOCOMOTIVES;
 and at the last trials of the Royal Agricultural Society of
 England their AGRICULTURAL LOCOMOTIVES gained
 the First Prize after exhaustive trials, when one of their 10-horse
 power Engines, fitted with single slide and ordinary link-
 motion, indicated 35-horse power, with a consumption of three
 and one-fifth pounds of coal per horse-power per hour.

STEVENS'
TRENTHAM GREENHOUSE BOILER,
 After long experience, has proved the most SIMPLE,
 ECONOMICAL, EFFECTUAL, and LASTING BOILER
 extant; recently improved.

Copy of a Testimonial.

"Messrs. SILVESTER, Royal Exotic Nursery, King's Road,
 Chelsea, S.W.—Aug. 8, 1877.
 "GENTLEMEN,—In reply to your enquiry as to our opinion
 of your Stevens' Trentham Boilers, we do not hesitate to pro-
 nounce them to be by far the best Boilers we have ever used.
 Our establishment is a very large one, and we have tested most
 of the various descriptions of Boilers which have been brought
 out from time to time. We originally commenced with one Tren-
 tham Boiler, and we have now thirteen of various sizes at work.
 For certainty of action, economy in fuel, and freedom from
 breakdown, we have never had a Boiler at all equal to the
 Stevens' Riveted Trentham Boilers supplied by you, and
 we have never felt so little anxiety in connection with our hot-
 houses during the cold winter months as we do now.
 "We are not in the habit of giving testimonials, but we
 think this may fairly be an exception to our rule, as the matter is
 one of such importance to the Gardening Public generally,
 and our experience has led us to form a very decided opinion.
 "We are, Gentlemen, yours faithfully,
 "JAMES VEITCH and SONS."
 For Illustrations, with full particulars, apply to the Sole Makers,
F. & J. SILVESTER,
 HOT-WATER ENGINEERS, &c., &c.,
 Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction
 and under the inspection of the inventor, Mr. Stevens—all
 others being base imitations.

WAGSTAFF'S
 Patent Saddle and
 Cylindrical
BOILERS.
 Efficient and Economical.
 Awarded 6 Silver Medals.

Messrs. E. G. HENDERSON & SONS' Spacious Nurseries,
 Pine-apple Place, Maida Vale, are most satisfactorily Heated
 with two of these Boilers.
 Plans and Estimates of Work in any part of the Kingdom
 gratis, and efficiency guaranteed. Price Lists, Prospectus, and
 Testimonials free on application.
THOS. WOLSTENCROFT and CO., 46, Ludgate Hill,
 LONDON, E.C.
J. G. WAGSTAFF, Albert Ironworks, Dukinfield.

STOVES,
 Terra-Cotta! Portable! For Coal!
ROBERTS'S PATENT.

Healthy Heat twenty-four hours or longer for about 1d.,
 without attention. For Bedrooms, Greenhouses, or almost any
 purpose. Prospectus and authenticated Testimonials sent. In
 use daily at Patentee's, THOMAS ROBERTS,
112, Victoria Street, Westminster, S.W.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle
 Boiler, with the following improvements—viz., the water-space
 at back and over top of saddle increases the heating surface to
 such an extent that a "PATENT DOUBLE L SADDLE
 BOILER" will do about twice the amount of work with the same
 quantity of fuel; the cost of setting is also considerably reduced,
 and likewise the space occupied; at the same time these Boilers
 are simple in construction, and being made of wrought iron are
 not liable to crack. They are made of the following sizes:—

Sizes.			To heat of	Price.
High.	Wide.	Long.	4-in. Pipe.	£ s. d.
20 in.	18 "	18 "	300	7 0 0
20 "	18 "	24 "	400	8 0 0
20 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	30 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
24 "	24 "	48 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Dalham Hill, S.W.,
 May 29, 1877.

"Having given your Patent 'Double L' Boilers a fair trial
 at my Nurseries, I beg to say that they are most satisfactory.
 I consider them the best in use, and without doubt the most
 economical of all boilers; they will turn the refuse of other
 tubular boilers I have in work."

PRICE LISTS of HOT-WATER PIPES and CONNEX-
 TIONS, with Boilers, of all sizes and shapes; or ESTIMATES
 for HOT-WATER APPARATUS, erected complete, will be
 sent on application.

J. JONES and SONS, Iron Merchants, 6, Bankside, South-
 work, London, S.E.

For Sale, a
STEVENS' IMPROVED TRENTHAM
 WROUGHT IRON HORTICULTURAL BOILER,
 6 feet long by 3 feet diameter, fitted with Inlet and two Outlet
 Pipes, Fire-door and Grate complete. For price and particu-
 lars apply to
HILL and SMITH, Brierley Hill Ironworks, Dudley.

AN EXTRAORDINARY BOILER.—
 During the Great Boiler Contest at Birmingham, in
 1872, all Boilers were severely tested to prove their respective
 merits. One test was, "How long can each Boiler go without
 Night Attention?" However, one Boiler proved this, to a sur-
 prising degree, as after being shut up for twelve hours (from
 9 P.M. to 9 A.M.), it still retained its heat in 1000 feet of 4-inch
 pipes, and yet had more than 1 bushel of fire drawn from its
 furnace in the morning—equal, in point of fact, to seventeen
 hours of continuous firing. What a boon to Gardeners. This
 was THE CHAMPION, Deards' Patent Close-Coil Boiler, for
 Drawings and Prices of which send two stamps to

Messrs. DEARDS, Boiler Works, Harlow,
 who now have their Boilers at work in every county of England
 except three. Amateurs will also find THE WONDER, a
 smaller kind of Boiler, equally as satisfactory, and certainly
 "the best thing" out. Awarded five First Prize Silver Medals.

NOTICE TO THE TRADE.
TEBBS' UNIVERSAL FUMIGATOR
 Can be obtained Wholesale of FLANAGAN and SON,

And 21, BACHELOR'S WALK, DUBLIN.
No AGENTS.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK

VARNISH for Preserving Ironwork, Wood, or Stone.
This Varnish is an excellent substitute for oil paint on all out-
door work, while it is fully two-thirds cheaper. It was intro-
duced upwards of thirty years ago by the advertisers, and its
genuine good quality, notwithstanding a host of unprincipled
imitators, is fully attested by its constantly increasing sale. It
may be applied by an ordinary labourer, requires no mixing or
thinning, and is used cold. It is used in the grounds at
Windsor Castle, Kew Gardens, and at the seats of many hun-
dreds of the Nobility and Gentry, from whom the most flattering
testimonials have been received, which HILL & SMITH will
forward on application.

Sold in casks of about 30 gallons each, at 12. 6d. per gallon,
at the Manufactory, or 12. 3d. per gallon carriage paid to any
Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.
"The Kyles, Alderly Edge, Manchester.—Messrs. Hill &
Smith,—Sir,—For some 20 years I have used your 'Black
Varnish,' and shall be glad if you will forward me another cask,
as I consider it the best thing known for the preservation of all
outdoor work, either wood or iron, that requires to be painted.
—Yours respectfully, ALFRED LOWR, J.P."

Apply to HILL and SMITH, Brierley Hill Ironworks, near
Dudley; and 118, Queen Victoria Street, London, E.C., from
whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of
HILL & SMITH that spurious imitations of this Varnish are
being offered by unprincipled dealers at a slight reduction in
price, they would especially draw attention to the fact that every
cask of their Varnish is legibly marked with their name and
address, without which none is genuine.

Notice.

(By appointment to the Royal Horticultural Society.)

To HORTICULTURAL IMPLEMENT MAKERS,
NURSERMEN, FLORISTS, and OTHERS.

KINAHAN'S LL WHISKY.

Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest agent for delicate Constitutions, Ladies, Children, and Infants.
 DINNEFORD AND CO.,
 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S OINTMENT and PILLS.

—Rheumatism and Gout.—These purifying and soothing remedies demand the earnest attention of all persons liable to gout, sciatica, or other painful affections of the muscles, nerves, or joints. The Ointment should be applied after the affected parts have been patiently fomented with warm water, when the unguent should be diligently rubbed upon the adjacent skin, unless the friction should cause pain. Holloway's Pills should be simultaneously taken to reduce inflammation and purify the blood. This treatment abates the violence, and lessens the frequency of gout, rheumatism, and all spasmodic diseases which spring from hereditary predispositions, or from any accidental weakness of constitution. This Ointment checks the local remedy. These Pills restore the vital powers.

UNSOLICITED TESTIMONIALS.

From H. T. HADERSHON, Esq., Wood-pen House, Newbury May 31.

"I purchased some Tulips and Crocuses of you last year, which have given me great satisfaction."

From C. B. HOBSON, Esq., Lindfield.

"The Miniature Hyacinths were very much admired by all who saw them. The flowers were extremely large and beautiful."

HOW TO GROW FLOWER ROOTS SUCCESSFULLY, SEE

"SUTTON'S AUTUMN CATALOGUE.—We have received from Messrs. Sutton & Sons their Autumn Catalogue of fresh imported bulbous Flower Roots, Plants, Seeds, &c. The collection of bulbs is very choice, and are strongly recommended as being most likely to thrive in any ordinary garden soil of good quality, but not particularly heavy, as most worthy of cultivation, and as the most showy and most certain to thrive with ordinary treatment. In this list are the best known varieties of the Single and Double Hyacinths, Tulips, Crocuses, Jonquils, Polyanthus, Narcissus, Gladiolus, and various kinds of Lily. The List of Hardy and Showy Plants, Climbers, &c., is also a full and satisfactory one. The Catalogue likewise contains some simple instructions as to soil and treatment, which will be found very serviceable to those uninitiated in the cultivation."—From "Land and Water," August 22.

Price 6d. Post-free, or Gratis to Customers.

"SUTTON'S AUTUMN CATALOGUE of fresh imported Bulbous Flower Roots, Plants, Seeds, &c.—We would engage attention for this elegant Catalogue, which Messrs. Sutton, of Reading have just issued. It is very compendious, and offers such a collection of Plants and Seeds as amateurs and others will be glad to possess to select from."—From the "Maguet," August 24.

"MESSRS. SUTTON'S CATALOGUE is a most valuable one, containing as it does not only Lists of the Choicest Varieties to Grow, but carefully prepared Notes on the Best Modes of Culture, conveyed in clear and precise terms. The Catalogue may indeed be pronounced a complete *vaude mecum* for the Villa Gardener, for the cultural instructions for every description of Bulbous Roots are evidently written by thoroughly practical hands. Armed with this Catalogue, the amateur cannot go astray either in his selections or mode of treatment of this beautiful tribe of plants, which are amongst the earliest arrivals of the year. The carefully-executed illustrations add greatly to the value of Messrs. Sutton's publication."—From "The Villa Gardener," September.

THE QUEEN'S SEEDSMEN,

Sutton Sons

An Important Property, well known as the Norwood Nurseries, situated on the south side of Norwood, in the occupation of Mr. W. E. Dixon, the owner.

NEASTON and SON are instructed by the Proprietor, who is leaving Beverly, to sell by AUCTION at the "Holderness Hotel," Beverly, on **THURSDAY, November 8**, at 3 o'clock P.M., and subject to conditions which may be inspected prior to the Sale, the valuable FREEHOLD PROPERTY known as the Norwood Nurseries, situate on the south side of Norwood, Beverly, in the immediate vicinity of the centre of the town, and consisting of a commodious Family Residence, containing spacious Drawing and Dining Rooms (the latter 24 feet by 16 feet), Library, two Kitchens, six Bed and two Dressing Rooms, two Offices, W.C., and the usual Domestic Offices; an extensive range of modern Buildings, consisting of Sale Shop, Warehouses, Offices, Stables, Coach House, Harness Room, Van Shed, &c.; noble Conservatory, of recent erection, and fitted on the most approved principles, size, 50 feet by 40 feet; thirteen Greenhouses, about 1750 feet in length, containing about 12,500 superficial feet of Glass, the whole heated by about 3,000 feet of 4-in. piping; four Potting Sheds, and the extensive and well laid out Nursery Grounds, the area of the whole being about 7250 square yards, with a frontage to Norwood of 87 feet or thereabouts.

The situation of the property is a most central one for the extensive business now being carried on, and the present Sale offers a most favourable opportunity for purchase to any person wishful to embark in the Nursery and Seed Business. The property is also well worthy the attention of Speculators and Others, as a large portion of the land might be utilised for Building Purposes. Early Possession can be given.

N.B.—This Sale does not include the Nursery Stock.

For plans and further particulars application may be made to the Auctioneers, Bowalley Lane, Hull; to Mr. W. E. DIXON, on the Premises; or to SHEPHERD, CRUST, TODD, and MILLS, Solicitors, Beverly.

Stanhope Nursery, Westerham Hill, Cudham, Kent. EXTENSIVE and VALUABLE NURSERY STOCK, comprising fine Specimen Shrubs, Fruit Trees, Standard and Dwarf Roses, Cedars, Deodars, Weymouth and other Pines, Portugal and Common Laurels, Hollies, Ivy, Creepers, and a large quantity of Forest Trees, &c.

MESSRS. BAXTER, PAYNE, AND LEPPER will sell by AUCTION, on the Premises, by order of Mr. A. Fairall, on **TUESDAY, October 30**, at 12 to 1 o'clock precisely, the above valuable NURSERY STOCK, comprising a very choice collection of many thousands of Trees and Shrubs.

May be viewed, and Catalogues obtained at the various Inns in the neighbourhood, at the place of Sale; and of BAXTER, PAYNE, AND LEPPER, Auctioneers and Land Agents, Town Hall, Bromley, Kent, and 157, Fenchurch Street, E.C.

Important Collection of Dutch Bulbs.

MR. ALFRED RICHARDS has received instructions from M. Ph. Van Noort (the Importer), to sell by AUCTION, without reserve, at the Whittington Nursery, Highgate Hill, N., on **SATURDAY and MONDAY, November 4 and 5**, commencing at 12 to 1 o'clock each day, an important lot of about 100,000 DUTCH BULBS, consisting of Double and Single Hyacinths, Double and Single Tulips, Narcissus, Crocuses, Crown Imperials, Anemones, and Snowdrops. Also STOVE PLANTS, comprising Dracaenas, Crotons, Ficuses, and a variety of Ferns, &c.

May be viewed the day preceding and morning of Sale, Catalogues obtained at the Whittington Nursery, and of the Auctioneer, High Road, Tottenham.

The Potteries, Ilkeston.

To NOBLEMEN, GENTLEMEN, NURSERYMEN, FLORISTS, and OTHERS.

MR. WRIGHT LISSETT begs to announce that he is honoured with instructions from Richard Evans, Esq., to sell by AUCTION, at his Gardens, the Potteries, Ilkeston, on **MONDAY, November 5**, at 11 o'clock precisely, the whole of his very choice collection of CAMELLIAS, STOVE and GREENHOUSE PLANTS, and FERNS; also all the HOTHOUSES, GREENHOUSES, and a splendid CONSERVATORY, with the Heating Apparatus and Fittings belonging to each, likewise sixty-four GREENHOUSE LIGHTS, 7 feet 6 inches by 4 feet, quite new, suitable for Garden Frames; quantity of FLUE COVERS 18 by 9 inches, ditto, 18 by 12 inches; patent Garden ROLLER, by Tindale; large Iron TANK, and various other items.

The Camellias, for which Mr. Evans has long been noted, are in robust health, and well set with bloom, and are altogether a very fine collection, as well as the largest in the district for many miles round. The conservatory is nearly new, of artistic beauty, and in good condition, built from a design by Mr. Foster. One of the Vineries is equal to new.

Catalogues will be ready seven days prior to the Sale, and may be had at the place of Sale, and of the Auctioneer at his offices, Town Hall, Ilkeston, and Maypole Yard, Nottingham, on Saturdays.

Swiss Nursery, Loughborough Road, Brixton, S.W. (Close to the Loughborough Junction Station).

MR. W. ABRAHAM is instructed to sell by AUCTION, on the Premises, as above, on **SATURDAY, November 17**, at 1 o'clock punctually, a choice and varied assortment of NURSERY STOCK, including some fine Cryptomeria elegans, Junipers, Yew, Pampas Grass, Cupressus, Gold and Silver Holly, Standard and Dwarf Roses, Conifers and Evergreens in pots, large Myrtles, Palms, Agave, Oleander, trained, pyramidal and bush Fruit Trees, and many others.

Catalogues one week before the Sale, on the Premises; or of the Auctioneer, Goldworth Nursery, Woking, Surrey.

London, North-West District (4297).

TO BE SOLD, on Advantageous Terms, a small FLORIST'S BUSINESS. Excellent position, 2 miles from Covent Garden, adjoining a Railway Station. Comprises 2 acres of very productive Land. Lease eighteen years unexpired. Rent, £40 per annum. Income moderate. Stock and Glass by valuation. No reasonable offer refused. For further particulars apply to PROTHEROE and MORRIS, 98, Gracechurch Street, London, E.C.

In the Midland Counties (4317).

To NURSERYMEN, MARKET GARDENERS, FLORISTS and SEEDSMEN.

TO BE DISPOSED OF, a capital BUSINESS in a large and busy Market Town, with excellent railway facilities. Satisfactory reasons given. Comprises 8½ Acres of deep, rich, Nursery and Market Garden Land, convenient Dwelling-house and Seed Shop, 13 Greenhouses, ample Outbuildings. Manure and Sewage ready to hand for nothing. Lease nine years unexpired. Rent very moderate. Price required for Business and Stock may be obtained of Messrs. PROTHEROE and MORRIS, 98, Gracechurch Street, E.C.

London, North-West District (4320).

FOR DISPOSAL, in an excellent neighbourhood, a particularly genuine SEED and CUT FLOWER BUSINESS, comprising a desirable Ten-roomed Residence with commanding Shop. The present trade, which has not changed hands for thirty years, is a most lucrative one, and is being relinquished solely on account of ill-health. Lease eighteen years unexpired. Rent £35 per annum. Price for Lease, Goodwill, Fixtures, Stock on application to PROTHEROE and MORRIS, Horticultural Agents, 98, Gracechurch Street, London, E.C.

London (4316).

Ten Miles therefrom, facing an important Station on the South-Eastern Line.

A SMALL FLORIST'S and MARKET GROWER'S BUSINESS, in good going order, comprises a Cottage, 13 Greenhouses and Firs heated by hot-water. Held at a low aggregate rental of £37 per annum. Price required for Tenant's Fixtures, including nearly the whole of the Glass, together with the interest in the Lease, Stock, and Utensils in Trade, £550.

Apply to Messrs. PROTHEROE and MORRIS, Horticultural Agents, 98, Gracechurch Street, E.C.

To Nurserymen, Florists, and Others.

TO BE LET, with Immediate Possession, CRESCENT ROAD GRAPERIES, Worthing, standing on an acre and a quarter of ground. Nearly 500 feet run of Glass; 4000 Cottages. No Valuation on entering. For particulars or for view, apply to GARDENER, The Graperies, Crescent Road, Worthing.

Cheltenham—To Florists and Gardeners.
TO BE LET, the old-established NURSERY BUSINESS, London Road, Cheltenham, comprising good Dwelling House, gas laid on; five Greenhouses, 40 to 60 feet long; long range of Pits, the whole well heated by hot water; about 2 acre of Land planted with Violets, Roses, and other plants. Stock consists of Camellias, Eucharis, Stephanotis, Azaleas, Gardenias, Ferns, early Pelargoniums, scarlet Geranium for winter flowering, for which, with other cut flowers, there is a great demand; also stock of Bedding Plants. No reasonable offer.
 For further particulars apply to **FOREMAN** on the Premises, Charlton Nursery, London Road, Cheltenham.

Important Notice.
FIFTY NURSERY, FLORIST, SEED, and MARKET GARDEN BUSINESSES to be disposed of. For particulars see **PROTHEOE AND MORRIS PRINTED MONTHLY LIST**, obtainable (gratis) at 98, Gracechurch Street, E.C.

THE IMPROVEMENT OF LANDED ESTATES,
 By DRAINAGE, ENCLOSING, CLEARING, THE ERECTION OF FARM BUILDINGS AND COTTAGES, WATER SUPPLY, &c.

The Land Loan and Emfranchisement Co.
 (Incorporated by Special Act of Parliament)
ADVANCES MONEY.
 1st.—To the OWNERS of SETTLED and OTHER ESTATES, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing and General Improvement of Landed Property in any part of the United Kingdom.
 2d.—To the OWNERS of SETTLED ESTATES in ENGLAND, for the Erection or Completion of Mansions, Stables, and Outbuildings, and for the Construction or Erection of Reservoirs, and other Works of a permanent nature, to supply Water for the use of the Estate, or for any other purpose.
 3d.—To LANDOWNERS generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.
 4th.—To INCUMBENTS, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.
 5th.—To COPYHOLDERS, for the Emfranchisement of Copyhold Lands.
 The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years.
 No investigation of the Landowner's Title is necessary. Forms of application, and all further particulars may be obtained of:
 Messrs. RAWLENCE AND SQUAREY, 22, Great George Street, Westminster, S.W., and Salisbury; of Messrs. ASHURST, MORRIS, CRISP, AND CO., 6, Old Jewry, London, E.C.; of Messrs. We can supply Foundation Plates—which form Ash-pit—and Smokestacks, if wanted, thereby doing away with the necessity for even a single brick in their erection.

	A	B	C	D	E
Foundation Plate ..	s. d.	s. d.	s. d.	s. d.	s. d.
Smokestack, Damper, and Spout-Door ..	35 0	45 0	60 0	75 0	90 0
Furnace and Ash-Pit, Frame and Doors; also Furnace Bars, Bearers, Dumb-Plate, &c. ..	30 0	40 0	50 0	60 0	70 0

Foundation Plates are arranged to heat the air before it is sent into the ash-pit at back, and furnace-doors to heat the air before its admission into the furnace, furnishing in fact two "hot-air" blasts to the furnace; the admission of large volumes of cold air being most injurious to the economical working of the furnace.

In preparation an entirely NEW SERIES of SEVENTY BOILERS, embracing a large variety suitable for small places, &c., and all specially adapted for low situations where shallow boilers are a necessity. Particulars on application.

WM. WRIGHT & CO.,
AIRDRIE, N.B.

Vines—Vines—Vines.

B. S. WILLIAMS begs to announce that his VINES this year are in unusually fine condition, and are now ready for distribution.

NEW LATE-KEEPING BLACK GRAPE, "ALNWICK SEEDLING." This Grape was exhibited before the Fruit Committee, South Kensington, February 6, 1876, under the name of Clive House Seedling, a name the Committee have since thought fit to alter. The following is the description given by the Fruit Committee:—"It is a seedling between the Black Morocco and an unnamed variety raised at Wortley. The bunch shown was of fair size and well shouldered, and the berries large, oval in form, and jet black in colour, with a thick skin. The flavour was decidedly good, partaking of the rich sparkling flavour of the Black Morocco, but much sweeter. It has kept well till February, and will, no doubt, keep longer and prove a better Grape for general cultivation than the Black Alicante." This has been awarded a First-class Certificate. The stock offered is from the original plant. Early orders are respectfully solicited, as the stock is limited. Price 21s. and 42s. each. For Detailed List see BULB CATALOGUE.

NEW FIG, "HARDY PROLIFIC."—The fruit of this hardy Fig is about the medium size, Pear-shaped, rather tapering towards the stalk. The flesh is very sweet and luscious. It was introduced from France some few years ago, and has proved itself perfectly hardy. It must become a general favourite, as it is a very abundant bearer, either in pots or in a cold house, as well as on an open wall. It also ripens earlier than any other variety we know of. Price 10s. 6d. each. Extra sized fruiting plants, 21s. each.

B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London, N.

Vines and Strawberries.

"Plant now to ensure a full crop of fruit next season."

FRANCIS R. KINGHORN begs to announce that his stock of VINES, including all the leading varieties, is very extensive, and in excellent condition this season. The Canes are very fine, well ripened, and perfectly free from disease. Strong Planting Canes, 3s. 6d. to 5s. each; strong Fruiting ditto, 7s. 6d. to 10s. 6d. each.

Also his collection of STRAWBERRIES includes all the most popular kinds, and are ready for immediate planting. Price, in small pots, 16s. to 20s. per 100; from the open ground, 3s. to 5s. per 100.

Less numbers than 100 of any variety can be had, if desired. Prices to the Trade and LIST'S post-free, on application. Sheen Nursery, Richmond, Surrey.

Rhododendrons.

ISAAC MATTHEWS AND SON have to offer the following RHODODENDRONS—100,000 fine bushy plants, thinly grown and well rooted, nice round plants:—

RHODODENDRON SPLENDIDUM, white, 1 to 1 1/2 foot, 37s. 6d. per 100; 1 1/2 to 2 feet, 50s. per 100; 2 feet, 60s. per 100.

CAUCASICUM PICTUM, scarlet, 1 to 1 1/2 foot, 50s. per 100; 1 1/2 to 2 feet, 60s. per 100.

JACKSONII, scarlet, 1 foot, 50s. per 100; 1 to 1 1/2 foot, 60s. per 100; 1 1/2 to 2 feet, 75s. per 100.

WOOLLERII, scarlet, 1 to 1 1/2 foot, 60s. per 100; 1 1/2 to 2 feet, 65s. per 100.

HYBRIDS, from all choicest named varieties, 1 foot, 20s. per 100; 1 to 1 1/2 foot, 30s. per 100; 1 1/2 to 2 feet, 40s. per 100; 2 to 2 1/2 feet, 60s. per 100.

PONTICUM, 9 to 12 inches, 50s. per 1000; 12 to 15 inches, 10s. per 100; 15 to 18 inches, 15s. per 100; 18 to 21 inches, 40s. per 100; 2 to 3 feet, 50s. per 100.

YEW, English, 6 to 9 inches, 40s. per 1000; 9 to 12 inches, 50s. per 1000; 12 to 15 inches, 70s. per 1000.

English, bushy, 15 to 18 inches, 20s. per 100; 1 1/2 to 2 feet, 30s. per 100; 2 to 2 1/2 feet, 60s. per 100.

English, very bushy, 2 1/2 to 3 feet, 60s. per 100.

CURRENTS, Black, very strong, 10s. per 100.

GOOSEBERRIES, strong, 10s. to 12s. 6d. per 100.

CATALOGUES can be had on application to The Nurseries, Milton, Stoke-on-Trent.

MR. A. VAN GEERT, NURSERYMAN, Ghent, Belgium, begs to offer fine Plants of Budded CAMELLIAS, Indian AZALEAS, Ghent AZALEAS, LATANIAS, CHAMÆROPS, PHENIX and other PALMS, table sizes; also SPIRÆA JAPONICA, fine clumps. Prices on application.

The New CATALOGUE, just issued, sent to applicants.

New Exhibition and Decorative Fuchsias.
JAMES LYE, Clyffe Hall, Market Lavington, Wilts, has the pleasure to offer the following fine new varieties of his own raising, unrivalled for their high-class qualities, excellent habits, and free-flowering properties:—

DARK VARIETIES.

Charming. James Lye.
Gem of the West. Royal Standard.
Mr. James Huntley. Elegance.

LIGHT VARIETIES.

Beauty of Wilts. Mrs. Huntley.
Letty Lye. Delicata.
Flushing Bride. Miss Lye.

The above fine varieties have been most favourably reported on in the *Gardeners' Chronicle* for June 9, and the *Gardeners' Magazine* for June 23. A coloured illustration of Mr. James Huntley, Letty Lye, Mrs. Huntley, and Royal Standard, appeared in the *Floral Magazine* for October.

A Descriptive List can be had on application. Plants are now ready, and Orders will be executed as received.

Price, the set of twelve varieties, £1 10s.; per plant, 3s. Post-office Orders payable to

JAMES LYE, Market Lavington Office.

Alnwick Seedling Grape Vine.

D. P. BELL begs to offer young plants of the above Vine, the true variety as grown at Clive House, from which the only exhibit has been made, and for which he received the First-Class Certificate from the Fruit Committee of the Royal Horticultural Society, December 6, 1876, regarding which the report of the Committee, as given by the *Journal of Horticulture*, is as follows:—"The bunch is large and heavily shouldered, with a stout stalk. The berry stalks are stout, and the berries large and roundish oval, frequently with sutural furrows; skin quite black and membranous, covered with a fine bloom; flesh firm, tender, very juicy, and sweet. It was unanimously awarded a First-class Certificate. This is a far superior fruit to Alicante, and will no doubt prove to be a late-keeping variety of great value.

It is important that the public should know that this, the only authenticated variety (and therefore the original), has been exclusively raised at Clive House, and cannot be had elsewhere.

Plants 15s. each.
The fruit now hanging on the parent Vine may be seen on application.

SPECIAL NOTICE.

MUSHROOM SPAWN

(MILL-TRACK).

WM. CUTBUSH & SON

Have this Season a large supply of this Mushroom Spawn, which has been celebrated for very many years, and can only be obtained here, as it is manufactured under a peculiar process known exclusively to ourselves, and, wherever once used, no gardener will willingly take to any other kind. One chief feature in its superiority is the extraordinary length of time it continues to produce Mushrooms—many instances have occurred where beds have continued in full bearing for eight or nine months. The Mushrooms are also of a rich fleshy kind so much prized in the kitchen.

Printed Cultural Directions, with our Signature attached, will be enclosed in every Package.

For Price per Bushel, &c., see BULB CATALOGUE, Post-free on application.

Highgate Nurseries, N., and Barnet, Herts.

WM. CUTBUSH & SON

Invite an Inspection of their

GENERAL NURSERY STOCK,

Which is both extensive and of unusually fine quality.

In the Plant Department will be found—

- ERICA HYEMALIS
- ERICA GRACILIS
- ERICA WILMOREA
- ERICA SINDRYANA, and other winter-blooming varieties
- ERICAS, Hard-wooded varieties
- EPACRIS
- GENISTAS
- BOUVARDIAS
- SOLANUMS, beautifully berried and compact
- EPHYPHYLLUMS
- CYCLAMEN PERSICUM
- PRIMULA SINENSIS ALBO FL.-PLENO.

Splendid stuff, full of Bloom-buds.

GREENHOUSE PLANTS,

SUCH AS

- APHELEXIS, GENETYLLIS, ACACIAS,
- BORONIAS, PHÆNOCOMAS,
- DRACOPHYLLUM, ERIOSTEMON,
- CHOROZEMA, PIMELEA, &c.;
- DRACÆNA, GREVILLEA ROBUSTA,
- PALMS, FICUS ELASTICA;

FERNS,

Including ADIANTUM GRACILLIMA and other suchlike useful kinds;

- CAMELLIAS (English-grown), AZALEAS,
- TREE CARNATIONS, &c.

IN THE

HARDY DEPARTMENT,

Extending over Thirty Acres,

Will be found one of the most extensive Stocks of VARIEGATED and other choice HOLLIES in the Kingdom, and other

EVERGREEN and DECIDUOUS SHRUBS and ORNAMENTAL TREES;

Also FRUIT TREES of all descriptions, and STANDARD and DWARF ROSES.

Catalogues will be sent on application, post-free.

HIGHGATE NURSERIES, LONDON, N.,
And BARNET NURSERIES, HERTS.

**THOMAS'S
WROUGHT-IRON ESPALIER
TRAINERS,**

For Training Fruit Trees on the French System.

The arrangement of these Trainers is much improved, and is now rendered so simple that they can be readily fixed by inexperienced hands. The bases of the terminating and intermediate Standards are of Iron, and require neither Wood nor Stone to attach them to. The wires are usually placed about 8 in. apart.

REDUCED PRICES OF MATERIALS.
Galvanised Raidisseurs for Tightening the Wire.

Price 3s.  per dozen.

THE QUEEN'S SEEDSMEN, READING.

SATURDAY, OCTOBER 27, 1877.

TRUE AND FALSE MUSHROOMS.

OF all fungi the common Meadow-Mushroom (*Agaricus campestris*) is one of the easiest to determine. Its characters are so marked that, taken altogether, it is almost impossible to confound the Meadow-Mushroom with any other fungus. This statement may appear somewhat rash, when it is remembered that the varieties of the Mushroom are almost endless. In form, size, colour, and habit the Mushroom varies exceedingly, and runs into the adjoining species—the Horse-Mushroom (*A. arvensis*)—by such insensible gradations that it is sometimes impossible to see where the one ends and the other begins. Its taste varies with its

FIG. 100.—KEY TO COLOURED PLATE OF "TRUE AND FALSE MUSHROOMS."

size, colour, and habit; the richest and most delicious flavour is peculiar to the somewhat small, white-topped, pink-gilled Mushroom of our open pastures, and this characteristic flavour gradually diminishes until a much coarser flavour is reached in the yellow-topped, pink-grey-gilled Horse-Mushroom. The Mushroom of our markets, as supplied by professional Mushroom growers from spawn, is a kind of intermediate variety which cannot be referred to one or other of the two plants above-mentioned, but it is, as a rule, much more nearly allied to the Horse-Mushroom than the plant of the open meadows. In country markets the Horse-Mushroom is the variety commonly exposed for sale, and the Meadow-Mushroom less frequently appears, the former being far more common, and generally a heavier and bulkier plant.

The position of the Meadow-Mushroom on the coloured plate is indicated by the letter S in the accompanying outline (fig. 100), and the Horse-Mushroom by the letters T, V. The general average form and colour of the two plants can be seen on the coloured plate, but the decisive characters are best observed by cutting the plants through from top to bottom, as shown in fig. 101. The section displayed on cutting is virtually the same in both the Meadow and Horse-Mushroom. The salient characters consist in the cap being very fleshy, in the gills

being free from the stem, as at A (displaying a channel round the top of the stem when the uncut fungus is turned upside down), in the separable skin and edge of cap (see coloured plate), hanging down below the edge of gills at B, and in the collar which encircles the middle of the stem at C. A point of the first importance rests in the character of the gills not quite reaching the stem. The cap of the Mushroom is dry, never viscid, and may be silky, hairy, or scaly; it varies in colour from white to tawny, smoky, or it may even be of a darkish brown tint; the gills are at first whitish, then pink, or salmon, at length brown or black; the spores thrown down from the

FIG. 101.—SECTION OF THE TRUE MUSHROOM, *AGARICUS CAMPESTRIS*. (S, ON KEY.)

gills are brownish-purple or purple-black, and the stem is almost solid—not hollow. The Meadow-Mushroom sometimes shows a pink colour on being broken, and one variety turns almost blood-red; in another form the gills remain almost colourless, whilst in a third the top is more or less of a bright-purple colour. In the Horse-Mushroom the entire plant is larger and coarser; it prefers the neighbourhood of trees and hedges to the open pastures, the flesh changes more or less to dull yellow when cut or broken, the stem is more inclined to be hollow, and the gills are a dirty whitish brown, at length black. An entire volume might be written on the varieties of these two fungi, and the forms intermediate between them. Many of the forms have been named as varie-

FIG. 102.—*AGARICUS FASTIBILIS*. (W, ON KEY.)

ties, and sometimes these varieties are made to rank as species. Notwithstanding these variations of size, contour, and colour, the character found in the habit does not change, neither do the botanical characters found in the free gills, the hanging edge of cap, and the collar round the middle of the stem. In the Department of Botany at the British Museum may be seen carefully finished water-colour drawings by the writer of this article, of nearly every known variety of both Mushrooms. The consumption of *bonâ fide* Mushrooms is sometimes followed by indigestion, or some other unpleasant symptom. This is at times due to some peculiar idiosyncrasy of the consumer; at other times it is owing to some accidentally acquired property of the plant taken up during growth, or

to the presence of a parasitic mould, or it may be due to incipient decomposition having set in. Mushrooms and all other fungi should be perfectly fresh and clean when prepared for the table, and they should never be gathered from a rank or unclean position.

Experienced fungologists and observers of ordinary sharpness never confound any other fungus with the Mushroom, but careless, non-observant and ignorant persons often make the most surprising errors. Sometimes mechanics belonging to cities (and even country towns) make extraordinary mistakes, and try most hazardous experiments in fungus eating. I have more than once known instances of such persons eating minute fungi or consuming the crimson-topped and acrid *Russulæ* of our woods for Mushrooms.

The figures on the coloured plate represented by VV on outline belong to *Agaricus crustuliniformis*, and those indicated by W W pertain to *Agaricus fastibilis*. These two fungi are closely allied, and probably very dangerous, and they have a superficial resemblance to the Horse-Mushroom. I have several times seen them placed with Mushrooms in fungus exhibitions, and specimens have frequently been sent on to me as doubtful Mushrooms. Undoubtedly both plants somewhat resemble the Horse-Mushroom

FIG. 103.—*AGARICUS CERVINUS*. (X, ON KEY.)

in external appearance, but in character and habit they differ entirely. The habit is different, as the two dangerous fungi usually grow in woods and woody places, and not in pastures, and the odour is disagreeable instead of pleasant. The cap is moist or viscid, and not dry; the gills are not free, but attached to the stem (fig. 102, D). There is no hanging margin to edge of cap (E), there is no true ring round middle of stem (F), and the gills never become black. It must, however, be confessed that *A. fastibilis* and its near neighbours are very variable in all their characters, therefore one isolated point must not be taken by itself in this or any other fungus, but all the characters must be taken together. An article was recently published in the *Gardeners' Chronicle* recounting how *Agaricus fastibilis* had taken possession of a Mushroom bed in America. This was a most extraordinary case, and if such instances should ever become common Mushroom culture would cease altogether, owing to the superficial resemblance to be found between this plant and the bed Mushroom.

Agaricus cervinus (fig. 103) is represented on the coloured plate at X in key, and however much this fungus may appear unlike a Mushroom to the fungologist, yet it has often been placed with Mushrooms in exhibitions of fungi, and it is one of the plants commonly sent on to me as a possible or doubtful Mushroom. It resembles the Mushroom in its pink-coloured gills, which

are, as in the Mushroom, free from the stem (fig. 103, G). *A. cervinus*, however, has a different habit from the Mushroom, for it generally grows in woody places on and about stumps, though sometimes it certainly grows upon the naked ground, as do several of its neighbours. The plant is less fleshy in all its parts than the Mushroom, it has no hanging margin to its dry top at H, and, most important of all, it never has a collar round the middle of its stem (K). Its odour is not disagreeable, and the flesh remains white

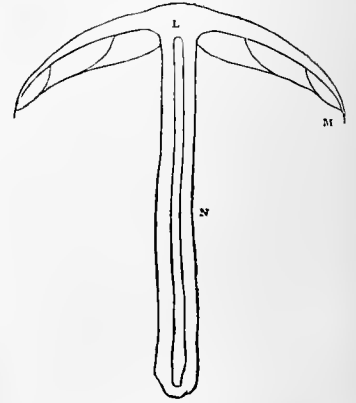

FIG. 104.—*AGARICUS VELUTINUS*. (V, ON KEY.)

when cut or broken, but (like all pink-spored *Agarics*, of which this is one), it is probably a dangerous fungus.

Agaricus velutinus (fig. 104), V on diagram, often puzzles beginners and not infrequently finds a place in the Mushroom gatherer's basket. Its qualities are imperfectly known, but like the next and last it has disagreeable and poisonous relations as neighbours, and therefore it may be looked upon with well-merited suspicion. Like the last, *A. velutinus* usually grows on and about stumps in woody places, and in garden

FIG. 105.—*AGARICUS LACRYMABUNDUS*. (Z, ON KEY.)

beds. It considerably resembles a slender Mushroom, though all its parts are more attenuated and brittle. It is far less fleshy (L) than a Mushroom, and it has a decidedly hollow or piped stem; it is furnished with a hanging margin or fringe round the edge of its dry cap, M, but the stem has no central collar, N. The flesh is stringy, and changes colour to yellowish brown when cut or broken; and the gills which are brown, purplish brown, or black, are commonly studded with drops of moisture.

The fungi represented at the bottom of the coloured plate, Z, Z on outline key, belong to *Agaricus lacrymabundus* (fig. 105). I have frequently known this fungus to be gathered for the true Mushroom, and it often (like the last) finds a

W.G. Smith ad nat del.

TRUE AND FALSE MUSHROOMS

place with Mushrooms for ketchup. It has many characters in common with the Mushroom, but it generally grows about stumps, though it is far from uncommon in bushy shady pastures and in gardens; it is somewhat less fleshy than the true Mushroom, it has a decidedly hollow or piped stem, flesh which changes to yellowish brown on being cut or broken, and a disagreeable odour. It generally has a ragged veil or fringe round the margin of its dry cap at O (fig. 105), and a ragged collar at P. In the attachment of the gills A. lacrymabundus differs from the Mushroom; for in the former plant the gills fairly reach the stem, Q, and therefore the characteristic channel left by the free gills of the true Mushroom is not to be seen.

It is very difficult to express in words the more delicate characteristic features of Agarics, and it is equally difficult to draw or paint the same features. Undoubtedly the characters exist in Nature, and an experienced fungologist will know, almost at a glance, the names and characters of from 500 to 1000 species of Agaricini. Sometimes, however, individual specimens of common species are very puzzling, as all Agarics have a great tendency to vary. A specimen of *A. terreus* puzzled the Woodhoopians at Hereford for some hours at their last meeting; a group of *A. inamoenus* and another of *A. velutinus* did the same. *A. lacatus* is so variable in its size, form, and colour, that its varieties might with some show of reason be referred to a dozen different species. It is impossible to know or study Agarics from herbarium specimens; they must be studied in the woods and fields.

Agaricus præcox, common in our gardens and fields in the spring, is sometimes mistaken for the Mushroom, as also are *Agaricus melaspermus* and *A. obturatus*, plants belonging to the woods and pastures of autumn. These three plants are at times mistaken for very small Mushrooms by persons unacquainted with fungi. *Worthington G. Smith.*

ROOT PRUNING.

THE theory and practice of root-pruning are now pretty generally understood; therefore, in directing attention to it now it is not needful to discuss the subject at length, but only to insist on the special necessity that has arisen for it at this time, owing to the exceptional character of the season. The excessive rainfall has encouraged an abnormal growth of more than ordinary succulency and size. Such wood is weak and ill-prepared to bear the strain of the coming winter, which is not unlikely to be one of much severity. Such mostly come on the heels of wet seasons. Watery wood and stinging frosts come badly together for the well-doing of the trees. The recent spell of dry weather came most opportunely to check or mature over-luxuriant growth, and even the unusual coldness of the weather may have rendered important service in this double capacity. But still the time is short, the growing season is nearly at an end, and as far as coming events casting their shadows before may be trusted, the winter will be an early one; therefore not a moment should be lost in root-pruning fruit trees as a means of completing the maturity of their wood.

There can be no doubt about the potency of root-pruning as a means of promoting the earlier and more perfect maturity of the wood and buds of fruit trees. Of course the sun's light and heat are the chief agents in this matter, but it is equally true that these influences are checked or hampered in their ripening operations by an excess of crude or watery sap. Cut off or limit the supplies of that, and the sun works with more freedom and potency. Solar influences are no longer handicapped by an excess of water or sap in the tree when that exists—it has been evaporated, got rid of before the work of ripening the wood and finishing fruit-buds can be set about. The sun force expended in dissipating the excess of water in the sap is lost for other and higher purposes, hence the importance in cutting off or curtailing the

supply of fluids by early root-pruning in such seasons as this. The very roots, too, that are generally singled out for severing or removal by the root-pruner are mostly those that raise most water. Without going very deeply into the physiology of root structure or function, the statement may be assumed to express a general truth, that the larger and simpler the structure of a root the more water it will raise. The converse is also true—that the more divided and fibrous the root the less water it probably sends to stem, branch, and leaf. We have hardly sufficient data concerning root function to enable us to advance a step further and assert that the fibrous roots forward the most and the best food, and the single undivided roots the least. But experience shows that fibrous-rooted trees ripen their wood sooner than those that are less branched, consequently root-pruning promotes maturity of wood and bud in two ways—it cuts off the excess of aqueous matter in the sap, and powerfully promotes that change of structure, if not of function, in the roots, that is most favourable to the ripening of the wood.

There is another obvious reason for root-pruning earlier and more severely than usual this season. The majority of fruit trees have borne little or no fruit. Freed from the burden of a crop, many of them have rushed into the making of more wood than usual. The sooner this abnormal vigour is checked the better for next year's fruit prospects; for it must be borne in mind that sterility has a tendency to repeat itself as well as fertility. Cultivators, as a rule, have not sufficiently recognised the operations of this law of like begetting like, even in such matters as fruit or no fruit. Few will deny the fact, though only those who are most familiar with root culture will be prepared to understand how it is that fruitful seasons and barren ones often seem to come in cycles. A free growth alone, with no crop to divert much of the vital force of the trees into fruitful channels, must of necessity result in a corresponding development of vigorous roots. These, if left unchecked, result in another crop of abnormally vigorous wood. The latter, again, results in the production of still more and larger roots, and so on and on to infinity; unless the exhaustion of the soil, the resistance of the subsoil, severities of climate, age or extension of parts, arrest the process of wood growing. The root-pruner, however, instead of waiting for such contingencies simply steps in and severs a few of the strongest roots, and thus forcibly arrests the dual processes of reciprocal wood and root-making, and compels the trees to set about the third and more valuable function of fruit bearing.

The sooner root-pruning is set about and completed the better. A caution may be needed against carrying the process too far. The temptation is strong when roots are exposed, after considerable labour, to prune them rather severely. This is seldom necessary or desirable. It is much better generally to raise up roots that are too low than to cut them off. Only the largest and most vertical roots should be cut off. The mere uncovering, and especially the detachment of the roots from the soil, is of itself almost as great a check as moderate pruning: for each root detached from its place of growth and what may, for lack of a better term, be designated its growing hold of the soil, is severely checked until it gets a new grip of the freshly moved or disturbed earth. It thus comes to pass that root-disturbance and examination may answer most of the purposes of root-pruning. A change in the place of roots, the raising them from a low to a higher level, may also bring about all the difference between a sterile and a fertile condition.

The character of the roots may also be modified by removal and a change of place—almost as much by a change of place and of soil as by cutting. By merely lifting large single roots nearer to the surface they often ramify into numerous fibres. From all which it follows that, while exposing the roots of trees with the ostensible object of pruning them, the amount of pruning to which they ought to be subjected, and even the prior question of whether they should be pruned at all, must be determined on the spot.

There is no operation that needs more judgment and care than root-pruning. The practice has often been brought into disregard

by the reckless mode of its performance. Some even perform it in the dark, and dispense as far as possible with the preliminary search for or careful examination of the roots. All roots are slashed off within a certain radius of the bole and a specified depth from the surface. Such operations may be designated almost hackings or choppings of the roots. As well send blind men to prune the tops of trees as thus hew their roots to pieces in the dark. Root-pruning needs to be as carefully performed as the most skilful forms of top-pruning, and opportunity should always be taken of the operation of pruning to train the roots also so as to avoid over-crowding, and to place each in the likeliest position for finding the most abundant supplies of the best food with the least risk of being preyed upon or overrun by the neighbouring roots.

Root-pruning, then, carefully performed, is an operation that may not be needful more than once in the life of most trees, and of it more than of almost any other cultural process it may be affirmed that what is worth doing at all is worth doing well; unless, in fact, done well it had better far be left undone. *F.* [We doubt the accuracy of our correspondent's dictum, that the larger the root the more water it will raise, and *vice versa*; and we have abundant evidence that a multitude of fibrous roots form better feeders than simple undivided roots. But these matters do not affect the practical side of our correspondent's article. EDS.]

New Garden Plants.

CYRIPEDIUM LUCIDUM, n. *hyb.* (*villosum* × *Lowii*)*

This is one more of Mr. Seden's highly curious hybrids, obtained at the Royal Exotic Nursery of Messrs. Veitch. It has the leaves just intermediate between those of the two species, narrower than in *C. Lowii*, and longer and stiffer than they are in *C. villosum*. There is a well defined narrow cartilaginous and lighter border. The peduncle would appear to be racemose, as I judge from my having obtained but a single flower without peduncle or bract. The flower has the cucurbit position of sepals and petals so very remarkable in *C. Lowii*. The upper sepal is greenish, with much brown at the base and in the middle, where there are very many brownish spots from which a brown middle line runs towards the apex. The inferior sepal is greenish yellow, rather narrow. The petals from a narrow base are much dilated, shining inside like the upper sepals, minutely ciliate, the superior half inside is brownish violet, the interior (basilar) part more yellowish, with very many brownish-violet spots at the base. The lip is nearly that of *villosum*, but chiefly brownish violet. There are, however, the small cartilaginous plates in the interior base of the sinuses of the horns with the channelled nail. The staminodium is nearly triangular, a middle tooth stands at its retuse anterior side, and the lateral parts are obscurely bilobe. There are many short violet hairs at its base and at its sides. The ovary is covered with whitish hairs. The mother plant is *C. Lowii*. *H. G. Rehb. f.*

SEDUM LYDIUM, *Boiss.*†

A pretty looking *Sedum*, which has for some years past found favour with gardeners who devote themselves to "carpet bedding." Its neat, close habit, and green colour, tending to red in hot seasons and dry places, render it admirably suited for the purpose in question.

We should hardly have thought it worth while to allude to it under this heading, but that the true name, *S. lydium*, has scarcely yet made its way into books on garden botany, and although the name occurs in some catalogues, yet it is difficult for any one not conversant with the technical literature of descriptive botany to verify the name or identify the plant. We have ourselves received the plant under the names of *S. lividum*, *S. pulchellum*, and *S. anglicum*—all three widely different plants.

* *Cyripedium lucidum*, n. *hyb.* (*Cyripedium villosum* × *Lowii*).—Folius ligulatis acutis valde coriaceis rigidis; pedunculo — bractea — ovario trigono villosa; sepalis superioribus oblongo obtuse acuto dorso carinato extus villosa; sepalis inferioribus optime connatis, anguste ligulatis, extus villosa; tepalibus lanceolato-ligulatis obtuse acutis, limbo minute ciliatis, valde vernixis; labello antice retuso, cornibus retrorsis bene evolutis; lamella utraque in sinu inter cornua et angustia; staminodio triangulo, dorso curvato, antice quinquelobato, lobo medio densifloro.—In herbo Veitchiano artificialiter excoltura. *H. G. Rehb. f.*

† *Sedum lydium*, *Boiss.*, *Diagn.*, ser. 1, 3, p. 17, et *Flor. Orientalis*, ii., p. 782.—*Glabrum cæspitosum; caudiculis repentibus; caulibus ascendentibus sterilibus abbreviatis dense foliosis; foliis linearibus obtusis; cyma corymboso-capitata radiis brevissimis densifloris scorpioides; pedicellis calyce brevioribus; petalis roseis lanceolatis obtusis; sepalis calyce laciniis oblongis obtusis subulpo longioribus.*—*Lydia et Caria, S. pulchellum et S. lividum hort. var.*

S. lydium is, as its name implies, a native of Asia Minor. Its barren shoots are 2 to 3 inches high, erect, and densely covered with alternate erect linear subterete green leaves about $\frac{1}{2}$ inch long, auricled at the base, blunt at the tip, and studded with small reddish tubercles, very pretty under a magnifying glass. The flowering shoots are 4—5 inches high, erect, with leaves of the same form as those on the barren stems, but less crowded. The flowers are numerous and borne on a corymbose cyme. The flower-buds are pentangular in outline. The expanded flowers are about $\frac{1}{4}$ inch in diameter, with oblong blunt reddish sepals; the petals are white or pale rose-coloured, oblong lanceolate. The stamens are double the number of the petals, those placed in front of the latter organs are adherent to them, and slightly longer than those placed in front of the sepals. The anthers are red. The ovaries are whitish or ultimately pink, surmounted by slender styles as long as themselves, and encircled at the base by small yellowish glands.

It is a charming little plant, well suited for rock-work, for covering places where little else will grow, and for carpet-bedding purposes, on which account it is desirable that its true name and position should be put on record. *M. T. M.*

THOMAS RIVERS.

By the death of Thomas Rivers, of Sawbridgeworth, British horticulturists lose one of the greatest of experimental physiologists, as well as one of the greatest practical benefactors to their craft. Rose growers, fruit lovers, planters in particular, may revere his memory. A keen man of business, he was yet so imbued with the love of truth for its own sake that, though never neglecting the main chance, he has by his genuine enthusiasm, as well as by the systematic method which guided his proceedings, earned a high place among the small band of vegetable physiologists.

Thomas Rivers was born at Sawbridgeworth in December, 1798, and on the death of his father succeeded to the now famous nurseries, which have been in the occupation or possession of his family at least a century and a half. The love of horticulture was strong in him from early youth. The curiosity which in some boys manifests itself in birds'-nesting, insect-catching, and the like, showed itself very early in attempts to grow, raise, and propagate plants. As years rolled on the love of experiment manifested itself in attempts to improve various descriptions of Roses and fruit trees.

The record of his life and works may be best found in his own books, *The Rose Amateur's Guide*, *The Miniature Fruit Garden*, *The Orchard-House*, &c. The popularity of these little books was amazing; of the first a tenth, of the second an eighteenth, of the third a fifteenth edition was issued. These were not mere trade catalogues, of which an annual edition might be published, but excellent little practical treatises revised in the case of each edition, so as to include the last experiences of the author and his correspondents. Such was the extent of his observations and the amount of his knowledge, that insight into the future of pomology at least seemed as remarkable with him as his knowledge of the past. In him truly "did old experience attain to something of prophetic strain."

Our own columns from the commencement in January, 1841, till a few years since, teem with notices from his pen, and with the comments of others on his publications and his nurseries. He was always a valued contributor to our pages, and a handsome clock on his mantel-piece was laughingly pointed out by him as the "Chronicle," in allusion to a compliment paid to him in recognition of his services. The fullest and most complete account of his nurseries, with incidental allusions to the work done by the proprietor, is given in our volume for 1866, by Mr. D. T. Fish.

In this place we can but briefly allude to the more salient features of his career. Progress was the law of his life from the first, whether it was in Roses, in fruit culture, or in the raising of new fruits. As far back as 1841 we find him growing a fine plant of the "finest Azalea ever known," and so through life, till enfeebled by age and sickness, progress was his motto.

EXPERIMENTS WITH MANURES.

One of the earliest things to attract his attention was the question of manures. He made endless experiments with them. He was one of the first prominent advocates of the value of malt dust as a manure. For many trees, especially Elms, he showed the value of bone-dust. For Plums he advocated the use of salt. For Strawberries his experiments showed

that nitrate of soda (3 oz. to the square yard) was a valuable manure, preferable even to guano. On the other hand, nitrate of soda as an application to Roses he found to be not only useless, but often injurious on his soil.

ROOT-PRUNING, LIFTING, DOUBLE GRAFTING, ETC.

Somewhere about the year 1839 we find him strenuously advocating root-pruning as a means of inducing fertility, and preventing the growth of coarse sappy wood shoots. There was nothing absolutely new in this, indeed it was practised by the Romans, but it had very much fallen into disuse in this country, and it needed the impulse of his practical mind and experience to recommend it to our gardeners. A measure of this kind, involving serious mutilation, requires judicious carrying out. Recklessly or too frequently performed it may do more harm than good. We are not sure that harm did not arise in many cases from Rivers' advocacy of the practice. Root-pruners did not all possess his experience and his judgment. As he himself used to say, the public required to be told, and told explicitly, that the proper end of a Cabbage to be put into the ground was the root end. Actuated perhaps by the consideration of the harm done by injudicious root-pruning, Rivers experimented largely on the lifting of fruit trees with the same object. This practice is less open to objection than root-pruning; and by inducing the formation of a leash of fine feeding-roots near the surface is often very advantageous.

Double grafting was another practice Mr. Rivers introduced to the notice of our horticulturists. In France it had been long practised under the name of *greffe sur greffe*. Pears that do not do well on the Quince, for instance, are double worked, that is, some other Pear, such as Gansel's Bergamot, is worked on the Quince, and in turn becomes the stock on which the desired variety is grafted. The object of the proceeding is to secure an equal growth of scion and stock and earlier and increased fertility. Seedling Peaches were treated in a similar way, being budded on the Plum stock, on the shoots of which latter the desired varieties are again budded.

STOCKS.

The question of stocks was ever one of the foremost objects of Rivers' attention. He rightly surmised that the habit, earliness, and productiveness of particular varieties, as well as their relative hardihood and suitability to particular conditions, depended in very great degree on the kind of stock employed, hence nearly forty years ago he introduced the Manetti stock from Italy. Its history is given in his *Rose Amateur's Guide*. The strong growth of the Manetti was found to make an excellent stock for Tea and China Roses, and to obviate in a great degree the evils arising from the production of suckers, to which the Brier is prone.

ROSES.

The culture and improvement of Roses early excited his interest, and secured for him well earned renown. "We all regard as our commander-in-chief," says the genial author of the *Book About Roses*, "that veteran hero Rivers, of Sawbridgeworth. . . . Age cannot wither his loyalty, and beneath a hundred medals, orders, and clasps, his brave heart is still with the Rose." At the age of twenty he considered himself the most dexterous and rapid budder of Roses that ever lived and was likely to live. Before his time standard Roses were imported from France, but Rivers went to the hedgerows for his stocks, and rendered himself independent of French supplies so far as these were concerned. The *Rose Amateur's Guide* is replete with sound information and historical detail, not the least interesting at the present time being the account of the beautiful hybrid China Rose, Rivers' George IV., which he raised about 1840, and which he says probably contributed more than anything to make him an enthusiastic Rose cultivator. The bright crimson-scarlet hybrid climbing Rose, named Sir John Sebright, was also raised by him at Sawbridgeworth from Italian seed. Mr. Rivers did not raise many new Roses, but he was a large introducer of new French varieties, and records with evident delight how, so far back as 1849, he sent out no less than 3000 standards and dwarfs of the glorious old *Géant des Batailles*, one of the progenitors of many of the best Roses of the present day.

The following extract from his catalogue of Roses for the present year is worth quoting from the point

of view just named:—"In the *Gardeners' Magazine* for August, 1833, Mr. London, the gardener's best friend, takes occasion to say of the first, or nearly the first, edition of my catalogue of Roses, 'This we consider to be the most useful catalogue of Roses in the English language.' He then goes on to say, 'To convey an idea of the completeness of the collection we may mention that there are sixteen sorts of *Rosa indica odorata*' (the tea-scented Rose). What a contrast this offers to catalogues of the present day, in which from sixty to eighty varieties of this class are named and described! In looking over a catalogue of the above date, printed on a single folio sheet, I find not even one variety of our favourite class, the Hybrid Perpetual, named."

ORCHARD HOUSES, ETC.

In the construction of houses for horticultural purposes efficiency and economy were the leading principles acted on by Mr. Rivers; houses and pits of weather boarding, covered with felt, with lights springing from a brick wall, or it might be from a thick hedge, were largely used by him. For everything that he did he had a good reason; the wood and the felt were not only cheap and effectual, but they allowed of rapid cooling by night, and in that way he endeavoured to imitate the Eastern climate, whence so many of our fruits have been derived, by securing a high day and a cool night temperature. The hedge-walls secured ventilation and prevented scorching; originally many of these houses were heated by an Arnott stove, with an evaporating pan at the top. But it was in the year 1851 that the orchard-house, with which his name will be ever associated, was first systematically introduced as a remedy for the fickle uncertainties of our spring climate. We have no intention of entering into the old controversy as to the value of these structures, the comparative advantages of pot culture, or of planting-out; suffice it to say that orchard-houses have become an established institution in the gardens of amateur horticulturists, and that their value under certain circumstances is no longer a matter of doubt. In the report of the Botanical Congress of 1866 is an excellent account of the mode of constructing and managing these houses and the fruit trees in them. In this paper, reproduced in our columns at the time, Rivers alludes with honourable pride to "orchard-houses—a term at first broached with diffidence, but now imbedded in the language."

Nor was this the only boon he conferred on the amateur gardener; ground vineries and similar structures for the protection of salads and other plants, if not absolutely introduced by him, were at least introduced more widely to public notice through him than they would otherwise have been.

RIVERS AS A POMOLOGIST.

But it is as a pomologist that Rivers will probably be longest remembered among us. It is not as a fruit cultivator that we have to speak of him, for we have had others greater than he; nor probably could he be compared with such as Thompson for an intimate knowledge of fruit nomenclature. But Rivers, from his own experience, had a wonderfully intimate knowledge of fruits, a special knowledge of some classes, "all his own," which he seemed never weary of imparting. No man in this country has done so much as Rivers in popularising the cultivation of fruits or in proving and introducing new or unknown sorts to our knowledge. It is not either to his introduction and advocacy of orchard-houses or the cultivation of fruit trees in pots that we would here allude, although assuredly they gave a great impetus to fruit growing, and perhaps tended in his own case in no small degree to make that possible for which his name will be long honoured and respected.

As a fruit hybridist, as the raiser and introducer of new fruits, the name of Rivers stands pre-eminent. We have had no English pomologist to compare with him at all in this department, if we except T. A. Knight. For the last quarter of a century and more there has been scarcely a season without some new fruits from Sawbridgeworth, and many of them have been very decided acquisitions, and are now popular and largely cultivated varieties. We subjoin a list of such new fruits raised and sent out by Rivers as we have been enabled to trace—probably very incomplete. The most remarkable are those in the Peach and Nectarine classes. In these quite a revolution has been effected. It is extremely interesting to note the parentage of some of these fruits—how some have

been bred "in-and-in," as it were, and others crossed. We have here accounts of Peaches raised from Nectarines, and of Nectarines from Peaches, proving that they are but varieties one of the other. In the Peach classes the great triumph achieved is the securing of the early varieties. By these Rivers has enabled us to extend our Peach season several weeks without giving any more trouble to the cultivator. This is a decided gain. What does it matter if these early sorts are not quite so large or so fine in quality as some of the mid-season fruits?—they are very good, and will remain a lasting honour to their raiser. The Princess Beatrice is considered the best early, Goshawk is a large and fine early sort, well worthy of cultivation. Of the late sorts not so much in favour can be said. The Princess of Wales and Lord Palmerston are both large and very showy fruits, but seldom of fine quality, partaking too much of the character of their parent, the Pavie de Pomponne. Of hardy varieties or improvements on old good sorts, we have Early York (Rivers), bearing glands, and consequently much hardier and not so susceptible to mildew as the old Early York, one of the discoveries, if we mistake not, of Rivers himself—the Alexandra Noblesse having a like distinction and qualification over the old Noblesse, &c. The mid-season varieties, although distinct, we do not consider equal to pre-existing standard sorts. In Nectarines the most wonderful advance has been made—nearly all of Mr. Rivers' seedlings being infinitely superior to the older sorts of the old varieties; none ever equalled in quality of flavour the Stanwick, but this was subject to one great blemish, that of the fruits cracking. Mr. Rivers, however, took advantage of this, and by judicious crossing succeeded in raising several varieties having all the good qualities of the Stanwick without its defects. We allude to the Victoria, which is perhaps the finest Nectarine in cultivation. It greatly resembles the Stanwick in every way, but does not crack. The Prince of Wales is another of the same sort, but later; and later still, the latest of all, is Albert Victor. Of the yellow-fleshed class Pine-apple is a great improvement on Pitmaston Orange. Another, of newer origin, is Lord Napier, a rather early, very large, and extremely handsome variety of excellent quality. This bids fair to be the leading Nectarine.

In the Plum classes several very important additions have also been received. Early Prolific, the earliest of all Plums, and a great bearer; Autumn Compôte, a first-class late cooking Plum; and Sultan, which bids fair to supersede the Prince of Wales, which it greatly resembles. If it does so, and frees us from the loss of trees which the cultivators of Prince of Wales Plum experience, it will be a gain.

The following list comprises some of the best known varieties originated at Sawbridgeworth:—

<i>Peaches.</i>	<i>Nectarines.</i>
Albatross	Prince of Wales
Alexandra Noblesse	Rivers' Elruge
Comet	Rivers' Orange
Condor	Rivers' White
Crimson Galande	Stanwick Elruge
Dagmar	Victoria
Dr. Hoag	
Early Albert	<i>Plums.</i>
Early Alfred	Autumn Compôte
Early Beatrice	Blue Prolific
Early Louise	Czar
Early Leopold	Early Favourite
Early Rivers	Early Rivers
Early Silver	Early Transparent Gage
Falcon	Grand Duke
Gladstone	Late Rivers
Golden Eagle	Late Prolific
Goshawk	Rivers' Early Apricot
Lady Palmerston	Rivers' Early Damson
Large Early Mignonne	Sultan
Lord Palmerston	
Magdala	<i>Pears.</i>
Merlin	Beacon
Nectarine	Fertility
Osprey	Princess
Prince of Wales	Seedling Bergamot
Princess of Wales	St. Swithen
Radcliffe	Summer Beurré d'Arenberg
Rivers' Early	
Sea Eagle	<i>Apricot.</i>
Stanwick Early York	New Large Early
<i>Nectarines.</i>	<i>Cherry.</i>
Advance	Early Rivers
Albert	
Albert Victor	<i>Raspberry.</i>
Byron	Autumn Black
Dante	
Darwin	<i>Strawberry.</i>
Downton Improved	Royal Hautbois
Humboldt	Seedling Eliza
Lord Napier	
Pine-apple	

SEEDLING FRUITS, ETC.

In an article in our columns in 1871 on seedling fruits we have a most interesting account from Rivers' own pen, wherein he speaks of raising seedlings as

exercising a fascination over him "which grew with my youth and has strengthened with my decline." The wonderful variations he had seen in fruits raised from seeds filled him with astonishment, and then he goes on to speak of his selections from Jefferson's and Reine Claude de Bayay Plums. Maoy hundreds of these were raised, and "all of great interest to the raiser, as the origin of all is given. It will be some years before all these trees bear fruit, but every season will give hope, and then disappointment, which one does not seem to feel, it is so often the lot of the fruit raiser." Speaking of seedling Plums he says:—

"It is now as nearly as possible fifty years since—I think I have told the tale, but *n'importe*—that my attention was attracted to some grand old Plum trees planted by my grandfather between 1770—1780. Their name, I think, was the Early French Plum. I soon found out that the proper name was *Précoce de Tours*. These trees, once in four or five years or so, bore good crops; in other seasons a mere sprinkling of fruit. By a sort of intuition it struck me that this tender but early Plum might be acclimatised by raising seedlings from it. Accordingly I sowed some stones, and raised some young trees. There were planted in a corner and nearly forgotten; I was then immersed in Rose culture. After some eight, or ten, or twelve years had elapsed, these trees commenced to bear fruit; I was struck by the precocity and goodness of one, and the great fertility and goodness of the other. They were first distinguished by their numbers, and were simply No. 1 and No. 2; after a few years the former was named the Early Favourite, a dessert Plum, and the latter the Early Prolific, at present the most popular of all Plums, not only for its earliness, for it is at market by the end of July, but for its excellent flavour as a preserve; it is when well grown and ripe far superior to any other early Plum, even as a dessert fruit. For the last twenty years it has so increased in popularity that from 15,000 to 20,000 trees are sold here annually, and some thousands of young pyramids are planted out 6 feet apart for bearing, under market-garden pruning. By raising this sort—creating it—one feels to have benefited one's species, and like growing the extra blade of grass, the feeling is one of gratification.

"About twenty-five years ago, when full of Rose love and Rose lore, I happened to be at Bellevue, a charming height near Paris—now, I think, devastated—on a visit to M. Laffay. In the midst of our Rose talk he said, 'You are so full of Roses, but look here—taste.' He then gave me a large mottled Golden Gage, with a most excellent and distinct flavour, superior, I then thought, to the old Green Gage; I think so still. This was Reine Claude Diaphane (now the Transparent Gage), because when fully ripe you can see the stone plainly. A few years after this time I received some trees, but they seemed so disinclined to bear that I despaired of them, their shoots were so glossy and vigorous, and their leaves the same, that no blossom-buds would form. This went on till the hot summer of 1857, I think, when some fine fruit ripened in September—how large and excellent they were! I was not, however, satisfied with the habit of the tree; it was too vigorous, and to a certain extent shy in bearing. My success in acclimatising the *Précoce de Tours* came to mind, and I had hopes. Some stones were sown, some young trees raised, and two years ago I had the pleasure of seeing a Plum of my own creating, likely, in a humble way, to immortalise my name (*cui bono?*). This seedling is a marvellous likeness of its parent as regards the colour, quality, and size of its fruit, but it ripens fully a month earlier, and is a great bearer; but, above all, instead of having smooth vigorous shoots, it has stout downy ones, and rugose leaves: a more complete departure from the parent I have never witnessed. One day this Plum will go to the London markets by thousands of bushels, and its raiser or creator may be remembered."

In the Congress report, to which we have before alluded, the subject of raising Peaches, Nectarines, and other fruits from seed is also treated at some length, and we are therein told how he formed the idea that varieties of fruit trees might be fixed from seed, and acquire the permanence of species. He tells of his disappointments with Apples and Pears, and of how he on the occasion of a glut in the market in the pre-railway days bought several bushels of Green Gages, and sowed the stones. Not one among the seedlings yielded a fruit worth a name, but all gave green fruit, so far bearing out his theory. He then narrates the history of the Early Prolific Plum, which is neither more nor less than the *Précoce de Tours*—vigorous in habit and abundantly prolific. "I felt," says he, "amply rewarded for my almost obstinate adherence to a somewhat speculative theory and for many years of careful culture."

In the same paper there is a brief account of his
